Balloon dilation of the eustachian tube for treatment of patients with chronic eustachian tube dilatory dysfunction is considered **investigational**.

### Policy Guidelines

The following codes may be used for this service:

- **69799**: Unlisted procedure, middle ear
- **C9745**: Nasal endoscopy, surgical; balloon dilation of eustachian tube

### Description

Eustachian tube (ET) dysfunction occurs when the functional valve of the eustachian tube fails to open and/or close properly. This failure is frequently due to inflammation and can cause symptoms such as muffled hearing, ear fullness, tinnitus, and vertigo. Chronic dysfunction can lead to hearing loss, otitis media, tympanic membrane perforation, and cholesteatomas. Balloon dilation of the ET is a procedure intended to improve the patency by inflating a balloon in the cartilaginous part of the ET to cause local dilation.

### Related Policies

- N/A

### Benefit Application

Benefit determinations should be based in all cases on the applicable contract language. To the extent there are any conflicts between these guidelines and the contract language, the contract language will control. Please refer to the member's contract benefits in effect at the time of service to determine coverage or non-coverage of these services as it applies to an individual member.

Some state or federal mandates (e.g., Federal Employee Program [FEP]) prohibits plans from denying Food and Drug Administration (FDA)-approved technologies as investigational. In these instances, plans may have to consider the coverage eligibility of FDA-approved technologies on the basis of medical necessity alone.

In September 2016, the AERA® (Acclarent) was granted a de novo 510(k) classification by the US Food and Drug Administration (FDA) (class II, FDA product code: PN2). The new classification
applies to this device and substantially equivalent devices of this generic type. The AERA® is cleared for dilating the eustachian tube in patients ages 22 and older with persistent ETD. In December 2016, the XprESS™ ENT Dilation System (Entellus Medical, Plymouth, MN) was cleared for marketing by the FDA through the 510(k) process (K163509). The FDA determined this device was substantially equivalent to existing devices for use in ETD. The predicate devices are XprESS™ Multi-Sinus Dilation System and AERA® Eustachian Tube Balloon Dilation System.

**Rationale**

**Background**

**Eustachian Tube Function**

The ET connects the middle ear space to the nasopharynx. It is approximately 36 mm long in adults. The ET ventilates the middle ear space to equalize pressure across the tympanic membrane, clears mucociliary secretions, and protects the middle ear from infection and reflux of nasopharyngeal contents.1 The tube opens during swallowing or yawning.

Eustachian tube dysfunction (ETD) occurs when the functional valve of the ET fails to open and/or close properly. This failure may be due to inflammation or anatomic abnormalities. ET dilatory dysfunction (ETDD) is most commonly caused by inflammation including rhinosinusitis and allergic rhinitis. ETDD can cause symptoms such as muffled hearing, ear fullness, tinnitus, and vertigo.2 Chronic ETDD can lead to hearing loss, otitis media, tympanic membrane perforation, and cholesteatomas.

**Epidemiology of ETD**

The epidemiology of ETD, including incidence and prevalence of the disorder and associated symptoms in the community, primary care, and referral populations, is not well-characterized. Data are also lacking to describe the natural history of the disorder and impact on patient functioning.

**Diagnosis and Outcome Measures**

There are no comprehensive guidelines regarding the diagnosis of ETD. In response to a National Institute for Health Research Health Technology Assessment (2014) concluding that an important limitation with available evidence for treatments of ETD is a lack of consensus on the definition and diagnosis,3 an international group of scientists and physicians with expertise in ET disorders developed consensus statements on ETD.1 The meeting was funded by Acclarent, a manufacturer of a dilation technology. The following summarizes relevant 2015 consensus statements from the group.

- There is no universally accepted set of patient-reported symptom scores, functional tests, or scoring systems to diagnose ETD.
- Diagnosis of ETDD should consider patient-reported symptoms along with evidence of negative pressure in the middle ear assessed by clinical assessment.
- Transient ETD is ETD with symptoms and signs lasting less than three months while chronic ETD is ETD with symptoms and signs lasting for more than three months.
- Future clinical trials should include outcomes related to patient-reported symptoms, otoscopy, tympanometry, and pure-tone audiometry, and outcomes should be assessed at baseline, in the short-term (6 weeks to 3 months) and the long-term (6-12 months).
- The 7-item Eustachian Tube Dysfunction Questionnaire is the only patient-reported outcome scale to have undergone initial validation studies.

Tympanometry is a frequently used outcome measure in ETD. Tympanometry measures the mobility of the tympanic membrane and graphically displays results in tympanograms. Tympanograms are classified by the height and location of the tympanometric peak. They are classified into three general patterns: type A indicates normal middle ear and ET function; type B indicates poor tympanic membrane mobility (“flat” tympanogram), and type C indicates the presence of negative middle ear pressure.4
The 7-item Eustachian Tube Dysfunction Questionnaire is used to assess ETD-related symptoms such as pressure, pain, “clogged” ears, and muffled hearing over the previous month. The seven items are rated by patients on a 7-level scale from 1 (no problem) to 7 (severe problem). The overall score is reported as a mean item score with a range from 1.0 to 7.0. The Eustachian Tube Dysfunction Questionnaire has been shown to be a valid and reliable symptom score for use in adults with ETD with an overall score of 2.1 or higher having high accuracy to detect the presence of ETD.5

Other important outcomes for evaluating a treatment for ETD are hearing outcomes, otitis media, clearance of middle ear effusion, tympanic membrane retraction, and quality of life. Another important consideration is the need for additional treatment, e.g., additional surgical procedures (including reintervention).

**Treatment of ETD**

Medical management of ETD is directed by the underlying etiology: treatment of viral or bacterial rhinosinusitis; systemic decongestants, antihistamines, or nasal steroid sprays for allergic rhinitis; behavioral modifications and/or proton pump inhibitors for laryngopharyngeal reflux; and treatment of mass lesions. Although topical nasal steroids are commonly used for ETD, triamcinolone acetonide failed to show benefit in patients ages 6 and older presenting with otitis media with effusion and or negative middle ear pressure in a randomized, placebo-controlled, double-blind trial published (2011).6

Patients who continue to have symptoms following medical management may be treated with surgery. Available surgical management includes myringotomy with the placement of tympanostomy tubes or eustachian tuboplasty. There is limited evidence and no randomized controlled trials supporting use of these surgical techniques.7 Norman et al (2014) reported that eustachian tuboplasty (other than balloon dilation) has been evaluated in 7 case series and was associated with improvement in symptoms in 36% to 92% of patients with low rates (13%-36%) of conversion to type A tympanogram (which is normal). Myringotomy and tympanostomy have been evaluated in two case series and were associated with symptom alleviation in a subgroup of patients.7

**Balloon Dilatation of the ET**

Balloon dilation is a tuboplasty procedure intended to improve the patency of the cartilaginous ET. During the procedure, a saline-filled balloon catheter is introduced into the ET through the nose using a minimally invasive transnasal endoscopic method. Pressure is maintained for approximately two minutes after which the balloon is emptied and removed. The procedure is usually performed under general anesthesia.8,9

**Literature Review**

Evidence reviews assess the clinical evidence to determine whether the use of technology improves the net health outcome. Broadly defined, health outcomes are the length of life, quality of life, and ability to function—including benefits and harms. Every clinical condition has specific outcomes that are important to patients and managing the course of that condition. Validated outcome measures are necessary to ascertain whether a condition improves or worsens, and whether the magnitude of that change is clinically significant. The net health outcome is a balance of benefits and harms.

To assess whether the evidence is sufficient to draw conclusions about the net health outcome of technology, two domains are examined: the relevance, and quality and credibility. To be relevant, studies must represent one or more intended clinical use of the technology in the intended population and compare an effective and an appropriate alternative at a comparable intensity. For some conditions, the alternative will be supportive care or surveillance. The quality and credibility of the evidence depend on study design and conduct, minimizing bias and confounding that can generate incorrect findings. The randomized controlled trial (RCT) is preferred to assess efficacy; however, in some circumstances, nonrandomized studies may be...
adequate. RCTs are rarely large enough or long enough to capture less common adverse events and long-term effects. Other types of studies can be used for these purposes and to assess generalizability to broader clinical populations and settings of clinical practice.

**Balloon Dilation for Eustachian Tube Dysfunction**

**Clinical Context and Test Purpose**

The purpose of balloon dilation of the eustachian tube (ET) is to provide a treatment option that is an alternative to or an improvement on existing therapies, such as continued medical management, mechanical pressure equalization device, tympanostomy, and eustachian tuboplasty other than balloon dilation in patients with chronic ETDD despite medical management.

The question addressed in this evidence review is: does balloon dilation of the eustachian tube improve the net health outcome in patients with chronic ETDD?

The following PICOTS were used to select literature to inform this review.

**Patients**

The relevant population of interest are individuals with chronic ETDD despite medical management.

**Interventions**

The therapy being considered is balloon dilation of the eustachian tube.

**Comparators**

Comparators of interest include continued medical management, mechanical pressure equalization device, tympanostomy, and eustachian tuboplasty other than balloon dilation. Treatment for chronic ETDD includes decongestants, antihistamines, and in some cases steroid nasal sprays.

**Outcomes**

The general outcomes of interest are symptoms, change in disease status, quality of life, and treatment-related morbidity. The 7-item Eustachian Tube Dysfunction Questionnaire (ETDQ-7) is a validated, standardized, 7-item patient-reported questionnaire to assess symptom severity associated with ETDD. The seven questionnaire items cover the following ear symptoms: pressure, pain, feeling clogged, cold/sinusitis problems, cracking/popping, ringing, and muffled hearing. Each item is assessed on a scale of one (no problem) to seven (severe problem), and an overall score, which is the mean of the seven item scores, is calculated. Scores in the range of one to two indicate no to mild symptoms, three to five indicate moderate symptoms, and six to seven indicate severe symptoms. Patients may also undergo middle ear functional assessments such as tympanometry, otoscopy, and performance of the Valsalva maneuver.

**Timing**

The existing literature evaluating balloon dilation of the eustachian tube as a treatment for chronic ETDD despite medical management has varying lengths of follow-up, ranging from 3, 6, 12, or 18 months. While studies described below all reported at least one outcome of interest, longer follow-up was necessary to fully observe outcomes.

**Setting**

Patients with chronic ETDD despite medical management are managed by otolaryngologists and primary care providers in an outpatient clinical setting.

**Study Selection Criteria**

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs;
b. In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies.

c. To assess long-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.

d. Studies with duplicative or overlapping populations were excluded.

**Systematic Reviews**

The evidence for balloon dilation for ETD consists of case series, systematic reviews of these case series, and two RCTs. Recent systematic reviews and meta-analyses are summarized in Tables 2 and 3. Huisman et al (2018) provided pooled results while Hwang et al (2016) provided qualitative summaries only. Most selected case series provided a follow-up of less than a year. One series with 78 patients had a mean of 12 months of follow-up, and another with 37 patients had a mean of 18 months of follow-up. All case series reported that patients experienced improvement when comparing symptoms before and after balloon dilation. The selected studies differed concerning other treatments for ETD used before and after balloon dilation. In Huisman et al (2017), revisions due to failure of the first ET balloon dilation procedure were reported in 3 of the 15 studies (n=714 patients); 122 revisions were reported.

c Per tympanometry.

d Number of patients.
Randomized Controlled Trials

Poe et al (2017) published the results of an RCT that compared balloon dilation of the ET with ET balloon catheter (ETBC) plus medical management to medical management alone. The balloon catheter used in the trial was a custom-designed ETBC (Acclarent). The RCT results are also described in the AERA (Acclarent) de novo summary from the Food and Drug Administration. The RCT characteristics, key results, and evidence gaps are summarized in Tables 4 through 7.

Eligible patients in Poe et al (2017) had persistent patient-reported symptoms of ETD (ETDQ-7; mean item score, ≥2.1) and abnormal tympanometry (type B or type C), and failed medical management including either a minimum of 4 weeks of daily use of an intranasal steroid spray or a minimum of one course of an oral steroid. Each investigator was required to perform three successful ETBC procedures in nonrandomized “lead-in” patients who were then followed for durability and safety outcomes. Randomization and analyses were performed at the person-level whether or not the patient had unilateral or bilateral ETD. The primary efficacy outcome (normalization of tympanometry) was assessed by both site investigators and a blinded, independent evaluator; discrepancies were resolved by a second independent evaluator. For bilaterally treated patients, both ears had to be rated as normalized for that patient to be considered normalized for the primary outcome. Patients completed follow-up visits at 2, 6, 12, 24, and 52 weeks, but data from the 52-week visit have not been reported. Patients in the medical management arm were allowed to receive balloon dilation of the ET after the six-week visit. Trial enrollment was stopped early after the second preplanned look when the prespecified O’Brien-Fleming stopping boundary for the primary outcome was crossed.

At baseline, the mean ETDQ-7 score was 4.7, 43% of patients had allergic rhinitis, and 61% of patients had at least 1 prior ear tube surgery. By the second interim analysis, 162 patients had been assigned to ETBC and 141 were included in the analysis; 80 had been assigned to medical management and 72 were included in the analysis. Patients were included in the analysis if they received the study treatment for which they were randomized and had six-week follow-up data. Approximately 52% of ETBC patients experienced tympanogram normalization at 6 weeks compared with 14% of medical management patients (p<0.001). The publication reported that sensitivity analysis was performed to test the robustness of results for the impact of missing data in the analysis cohort vs an intention-to-treat cohort, but the method of sensitivity analyses was not described. It was noted that there was a significant treatment by site interaction. Two sites had a higher percentage of tympanogram normalization for medical management subjects than for ETBC subjects while the remaining sites had higher normalization for ETBC. The prespecified secondary efficacy outcome (percentage with minimal clinically important difference change of 0.5 points on ETDQ-7) was not reported in the publication but was reported in the Food and Drug Administration summary. The minimal clinically important difference change in ETDQ-7 scores was observed for 91% of ETBC patients at 6 weeks compared with 45% of medical management patients (p not reported). Fifty-six percent of ETBC patients had an ETDQ-7 mean item score of less than 2.1 at six weeks compared with about 9% of medical management patients (p<0.001).

Comparative analyses were not possible after 6 weeks because 82% of medical management patients elected to ETBC after 6 weeks. The durability of the effect is supported by analysis of tympanogram normalization in 170 patients with week 24 data (98 randomized to ETBC and 74 from the lead-in); 62% of those randomized to ETBC and 58% of lead-in patients demonstrated tympanogram normalization at 24 weeks. Data from 52 weeks have not been reported.

Adverse events were only briefly described in the publication but are more fully described in the Food and Drug Administration summary. Two-hundred ninety-nine patients who were treated with ETBC were included in the safety analysis (80 lead-in patients, 149 patients randomized to ETBC, 70 patients randomized to medical management who received ETBC). There were 16 nonserious device or procedure-related adverse events in 13 patients; most commonly, epistaxis and ETD. Two patients had three potentially device-related adverse events.
mucosal tear worsened ETD and conductive hearing loss. The potential device- or procedure-related adverse events were mild or moderate in severity and resolved without sequelae. Five serious adverse events were reported (four events in the balloon dilation of the eustachian tube group, one event in the medical management group); all were thought to be unrelated to device, procedure, or medications.

Meyer et al (2018) published the results of a 1-year follow-up, inclusive, prospective, multi-center RCT of balloon dilation as a treatment for persistent ETD and compared the intervention to continued medical therapy (control). Inclusion criteria required patients to be diagnosed with medically refractory, persistent ETD. Participants were randomly assigned (1:1) to intervention or control; however, control participants were offered the intervention after six weeks if their symptoms remained. The outcomes measured include primary efficacy endpoints using the ETDQ-7 scores and the rate of complications. The trial involved 60 randomized participants (31 intervention, 29 control). Mean standard deviation change in overall ETDQ-7 score at 6 weeks was 2.9 (1.4) for balloon dilation compared with 0.6 (1.0) for control; balloon dilation was superior to control (p < 0.0001). No complications were reported in either study arm. Among participants with abnormal baseline assessments, improvements in tympanogram type (p < 0.006) and tympanic membrane position (p < 0.001) were significantly better for balloon dilation than control. Improvements in the ETDQ-7 scores were maintained through 12 months after balloon dilation. Limitations of this RCT are its small sample size and the inability to blind the participants to their treatment.

Tables 4 and 5 summarize key characteristics and results for these two RCTs.

**Observational Study**

Satmis et al (2018) published a retrospective cohort study of 42 consecutive adult patients with chronic ETDD. Patients in a tertiary referral hospital setting who received transnasal balloon dilation of the ET were evaluated. Objective outcome measures included the ETDQ-7 score, bone conduction threshold, and tympanic membrane and middle ear conditions, which were pre and postoperatively collected. Mean ETDQ-7 scores improved from 4.28 to 3.09 and from 4.10 to 2.96 postoperatively at 1 and 3 months respectively. There was a 62.0% improvement in the tympanic membrane and middle ear condition. No serious procedure-related complications were reported.
Section Summary: Balloon Dilation for ETD

Balloon dilation of the eustachian tube has been evaluated in case series, systematic reviews of case series, a retrospective cohort study, and two published RCTs. Most case series provided follow-up of less than a year and all showed short-term improvement comparing symptoms before and after balloon dilation. The number of revisions needed due to the failure of the initial ET balloon dilation procedure was reported in 3 case series (n=714 patients); 122 revisions were reported. In one published RCT, balloon dilation plus medical management was compared with medical management alone, with comparative data available at six weeks of follow-up. The trial was stopped early due to the significant benefit of the balloon dilation compared with medical management at the second preplanned analysis. A greater proportion in the balloon dilation group demonstrated tympanogram normalization (52%), the primary outcome, compared with the medical management group (14%) at 6 weeks and reported a reduction in symptoms at 6 weeks on a validated questionnaire, ETDQ-7. The tympanogram outcome was assessed by blinded evaluation, but the symptom scores were patient-reported, and patients were not blinded (i.e., there was no sham procedure); therefore, results could have been biased.

In addition, the study was stopped at 6 weeks because 82% of the medical management arm crossed over to the balloon dilation intervention when it was allowed at this point in the study. Intention-to-treat analyses were not shown, but a sensitivity analysis showing the robustness of the results to missing data was reportedly performed. There was variability in the treatment effect as 2 (of 21) sites did not show benefit for balloon dilation, which the investigators suggested could have been due to the device and procedural learning curve of the study staff or problems with protocol compliance. The rate of adverse events was low, and none of the serious adverse events was thought to be related to the device or procedure. The trial was designed to follow patients for 52 weeks, but long-term data have not yet been reported. The durability of effect, rates of reoperation or revisions, and safety data over the first year are needed. The second RCT enrolled patients with moderate to severe ETD based on the ETDQ-7, but who were not required to have abnormal middle ear functional assessments. Symptom score change was the primary outcome and mean score decrease was greater in the balloon dilation group than the medical management group. In both RCTs, the initiation, concomitant or continued use of medical therapy of multiple drug classes was at the discretion of the investigators.

Summary of Evidence

For individuals who have chronic ETDD despite medical management who receive balloon dilation of the ET, the evidence includes case series, systematic reviews of case series, a retrospective cohort study, and two RCTs. The relevant outcomes are symptoms, change in disease status, quality of life, and treatment-related morbidity. The criteria for diagnosing ETDD are not standardized. Several medical and surgical treatments are used for ETDD, but there is limited evidence for available treatments. Most case series assessed provided follow-up of less than a year and all showed short-term improvement comparing symptoms before and after balloon dilation. The number of revision procedures required due to the failure of the first ET balloon dilation procedure was reported in 3 case series (n=714 patients); 122 revisions were reported. In one published RCT evaluating balloon dilation of the ET, patients were eligible if they reported persistent ETDD symptoms as measured on the ETDQ-7, a tool to assess symptoms, and had an abnormal tympanometry. A greater proportion of patients in the balloon dilation group demonstrated tympanogram normalization (52%) compared with the medical management group (14%) at 6 weeks and reported a reduction in symptoms at 6 weeks on the ETDQ-7. The durability of effect at 24 weeks was demonstrated in a subset of patients. The rate of adverse events was low, and none of the serious adverse events were thought to be related to the device or procedure. The 52-week follow-up data have not been reported. The second RCT enrolled patients with moderate to severe ET based on the ETDQ-7 but who were not required to have abnormal middle ear functional assessments. Symptom score change was the primary outcome and mean score decrease was greater in the balloon dilation group than the medical management group. In both RCTs, the initiation, concomitant or continued use of medical
therapy of multiple drug classes was at the discretion of the investigators. The durability of effect, rates of reoperation or revisions, and safety data over the first year are needed. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Practice Guidelines and Position Statements**

**National Institute for Health and Care Excellence**

The National Institute for Health and Care Excellence (2011) published guidance on balloon dilation of the eustachian tube.16 The guidance stated:

“Current evidence on the efficacy and safety of balloon dilation of the Eustachian tube is inadequate in quantity and quality. Therefore, this procedure should only be used in the context of research, which should address the efficacy of the procedure in the short and longer term, and also document safety outcomes.”

**U.S. Preventive Services Task Force Recommendations**

Not applicable.

**Medicare National Coverage**

There is no national coverage determination. In the absence of a national coverage determination, coverage decisions are left to the discretion of local Medicare carriers.

**Ongoing and Unpublished Clinical Trials**

A January 2019 search did not identify any ongoing or unpublished trials that might influence this review.

**References**

**Documentation for Clinical Review**

- No records required

**Coding**

This Policy relates only to the services or supplies described herein. Benefits may vary according to product design; therefore, contract language should be reviewed before applying the terms of the Policy. Inclusion or exclusion of codes does not constitute or imply member coverage or provider reimbursement.

**IE**

The following services may be considered investigational.

**Policy History**

This section provides a chronological history of the activities, updates and changes that have occurred with this Medical Policy.
Definitions of Decision Determinations

Medically Necessary: A treatment, procedure, or drug is medically necessary only when it has been established as safe and effective for the particular symptoms or diagnosis, is not investigational or experimental, is not being provided primarily for the convenience of the patient or the provider, and is provided at the most appropriate level to treat the condition.

Investigational/Experimental: A treatment, procedure, or drug is investigational when it has not been recognized as safe and effective for use in treating the particular condition in accordance with generally accepted professional medical standards. This includes services where approval by the federal or state governmental is required prior to use, but has not yet been granted.

Split Evaluation: Blue Shield of California/Blue Shield of California Life & Health Insurance Company (Blue Shield) policy review can result in a split evaluation, where a treatment, procedure, or drug will be considered to be investigational for certain indications or conditions, but will be deemed safe and effective for other indications or conditions, and therefore potentially medically necessary in those instances.

Prior Authorization Requirements (as applicable to your plan)

Within five days before the actual date of service, the provider must confirm with Blue Shield that the member's health plan coverage is still in effect. Blue Shield reserves the right to revoke an authorization prior to services being rendered based on cancellation of the member's eligibility. Final determination of benefits will be made after review of the claim for limitations or exclusions.

Questions regarding the applicability of this policy should be directed to the Prior Authorization Department. Please call (800) 541-6652 or visit the provider portal at www.blueshieldca.com/provider.

Disclaimer: This medical policy is a guide in evaluating the medical necessity of a particular service or treatment. Blue Shield of California may consider published peer-reviewed scientific literature, national guidelines, and local standards of practice in developing its medical policy. Federal and state law, as well as contract language, including definitions and specific contract provisions/exclusions, take precedence over medical policy and must be considered first in determining covered services. Member contracts may differ in their benefits. Blue Shield reserves the right to review and update policies as appropriate.
