1.01.27 Electrical and Electromagnetic Stimulation for the Treatment of Arthritis

Policy Statement

Electrical or electromagnetic stimulation is considered investigational for the treatment of osteoarthritis or rheumatoid arthritis.

NOTE: Refer to Appendix A to see the policy statement changes (if any) from the previous version.

Policy Guidelines

• N/A

Description

Pulsed electrical and electromagnetic stimulation are being investigated to improve functional status and relieve pain related to osteoarthritis and rheumatoid arthritis that is unresponsive to other standard therapies. Electrical stimulation is provided using a device that noninvasively delivers a subsensory, low-voltage, monophasic electrical field to the target site of pain. Pulsed electromagnetic fields are delivered using coils placed over the skin.

Benefit Application

Benefit determinations should be based in all cases on the applicable contract language. To the extent there are any conflicts between these guidelines and the contract language, the contract language will control. Please refer to the member's contract benefits in effect at the time of service to determine coverage or non-coverage of these services as it applies to an individual member.

Some state or federal mandates (e.g., Federal Employee Program [FEP]) prohibits plans from denying Food and Drug Administration (FDA)-approved technologies as investigational. In these instances, plans may have to consider the coverage eligibility of FDA-approved technologies on the basis of medical necessity alone.

Regulatory Status

The BioniCare Bio-1000™ stimulator (VQ OrthoCare) was cleared for marketing by the U.S. Food and Drug Administration (FDA) through the 510(k) process in 1997 to deliver pulsed electrical stimulation for adjunctive treatment of osteoarthritis of the knee, then later for rheumatoid arthritis of the hand. The FDA originally determined that this device was substantially equivalent to transcutaneous electrical nerve stimulation devices. The manufacturer requested reclassification due to the fact that the target tissue is joint tissue, not nerve. In 2006, the FDA reclassified the device as a transcutaneous electrical stimulator for arthritis.¹ The BioniCare System consists of an electronic stimulator device with electrical leads placed over the affected area and held in place with a lightweight, flexible wrap, and self-adhesive fasteners. The battery-powered device delivers small pulsed electrical currents of 0.0-V to 12.0-V output. FDA product code: NYN.
The OrthoCor™ Active Knee System (OrthoCor Medical; acquired by Caerus Corp. in 2016) uses pulsed electromagnetic field energy at a radiofrequency of 27.12 MHz to treat pain. In 2009, the OrthoCor Knee System was cleared for marketing by the FDA through the 510(k) process and is classified as a short-wave diathermy device for use other than applying therapeutic deep heat (K091996, K092044). It is indicated for adjunctive use in the palliative treatment of postoperative pain and edema in superficial soft tissue and for the treatment of muscle and joint aches and pain associated with overexertion, strains, sprains, and arthritis. The system includes single-use packs (pods) that deliver hot or cold. The predicate devices are the OrthoCor (K091640) and Ivivi Torino II™ (K070541). FDA product code: ILX.

In 2008, the SofPulse™ (also called Torino II, 912-M10, and Roma3™; Ivivi Health Sciences, renamed Amp Orthopedics) was cleared for marketing by the FDA through the 510(k) process as a short-wave diathermy device that applies electromagnetic energy at a radiofrequency of 27.12 MHz (K070541). The device is indicated for adjunctive use in the palliative treatment of postoperative pain and edema in superficial soft tissue. The Palermo device (Ivivi Health Sciences) is a portable battery-operated device. FDA product code: ILX.

In 2017, the ActiPatch® (BioElectronics) was cleared for marketing by the FDA through the 510(k) process for nonprescription use for adjunctive treatment of plantar fasciitis of the heel and osteoarthritis of the knee. FDA product code: PQY.

With the exception of ActiPatch, nonprescription devices are not evaluated in this review.

### Rationale

#### Background

Electrical and electromagnetic stimulation are being investigated to improve functional status and to relieve pain related to osteoarthritis and rheumatoid arthritis that are unresponsive to other standard therapies. Noninvasive electrical stimulators generate a weak electrical current within the target site using pulsed electromagnetic fields, capacitive coupling, or combined magnetic fields. In capacitive coupling, small skin pads or electrodes are placed on either side of the knee or wrist. Electrical stimulation is provided by an electronic device that noninvasively delivers a subthreshold low-voltage, monophasic electrical field to the target site of pain. Pulsed electromagnetic fields are delivered via treatment coils placed over the skin. Combined magnetic fields deliver a time-varying field by superimposing that field onto an additional static magnetic field.

In basic research studies, pulsed electrical stimulation has been shown to alter chondrocyte-related gene expression in vitro and to have regenerative effects in animal models of cartilage injury. It is proposed that the device treats the underlying cause of the disease by stimulating the joint tissue and improving the overall health of the joint and that it provides a slow-acting, but longer-lasting improvement in symptoms. Therefore, pulsed electrical stimulation is proposed to be similar to bone stimulator therapy for fracture nonunion.

#### Literature Review

Evidence reviews assess the clinical evidence to determine whether the use of technology improves the net health outcome. Broadly defined, health outcomes are the length of life, quality of life, and ability to function - including benefits and harms. Every clinical condition has specific outcomes that are important to patients and managing the course of that condition. Validated outcome measures are necessary to ascertain whether a condition improves or worsens; and whether the magnitude of that change is clinically significant. The net health outcome is a balance of benefits and harms.

To assess whether the evidence is sufficient to draw conclusions about the net health outcome of a technology, 2 domains are examined: the relevance, and quality and credibility. To be relevant, studies must represent 1 or more intended clinical use of the technology in the
intended population and compare an effective and appropriate alternative at a comparable intensity. For some conditions, the alternative will be supportive care or surveillance. The quality and credibility of the evidence depend on study design and conduct, minimizing bias and confounding that can generate incorrect findings. The randomized controlled trial (RCT) is preferred to assess efficacy; however, in some circumstances, nonrandomized studies may be adequate. Randomized controlled trial are rarely large enough or long enough to capture less common adverse events and long-term effects. Other pulsed electrical stimulation studies can be used for these purposes and to assess generalizability to broader clinical populations and settings of clinical practice.

Clinical Context and Therapy Purpose
The purpose of pulsed electrical or electromagnetic stimulation is to provide a treatment option that is an alternative to or an improvement on existing therapies, such as pharmacological therapy and physical therapy, in patients with arthritis.

The question addressed in this evidence review is: Does the use of pulsed electrical or electromagnetic stimulation improve health outcomes in patients with pain related to osteoarthritis and rheumatoid arthritis?

The following PICO was used to select literature to inform this review.

Populations
The relevant population of interest is individuals with osteoarthritis and rheumatoid arthritis.

Interventions
The therapy being considered is pulsed electrical or electromagnetic stimulation. The various forms of stimulation involved in this type of therapy include pulsed electromagnetic fields, capacitive coupling, or combined magnetic fields. In capacitive coupling, small skin pads or electrodes are placed on either side of the knee or wrist. Electrical stimulation is provided by an electronic device that noninvasively delivers a subsensory low-voltage, monophasic electrical field to the target site of pain. Pulsed electromagnetic fields are delivered via treatment coils placed over the skin. Combined magnetic fields deliver a time-varying field by superimposing that field onto an additional static magnetic field.

Comparators
Comparators of interest include pharmacological therapy and physical therapy. Treatment for arthritis includes physical exercise, self-care, nonsteroidal anti-inflammatory drugs (NSAIDs), topical analgesics, and surgical interventions.

Outcomes
The general outcomes of interest are symptoms, functional outcomes, health status measures, and treatment-related morbidity.

The existing literature evaluating pulsed electrical or electromagnetic stimulation as a treatment for arthritis has varying lengths of follow-up as long as 1 year. While studies described below all reported at least 1 outcome of interest, 6 to 12 months duration of follow-up is desirable to assess outcomes.

Study Selection Criteria
Methodologically credible studies were selected using the following principles:
1. To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs;
2. In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies;
3. To assess longer-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.
4. Studies with duplicative or overlapping populations were excluded.

Review of Evidence
Electrical Versus Electromagnetic Stimulation

Systematic Reviews
Three systematic reviews have reached somewhat different conclusions on the use of electrical and electromagnetic field stimulation for treating knee osteoarthritis.

Yang et al. (2020) published a systematic review evaluating the effects of pulsed electromagnetic field therapy on pain, stiffness, physical function, and quality of life in patients with osteoarthritis. The meta-analysis included 15 small, sham- or placebo-controlled studies published between 1993 and 2016 (N=985 patients). Only 2 studies were deemed to be at low risk of bias. Overall, the quality of evidence was deemed low or very low. A statistically significant beneficial treatment effect was noted for pain (standardized mean difference [SMD], 1.06; 95% confidence interval [CI], 0.61 to 1.51), stiffness (SMD, 0.37; 95% CI, 0.07 to 0.67), and physical function (SMD, 0.46; 95% CI, 0.14 to 0.78), but not quality of life (SMD, 1.49; 95% CI, -0.06 to 3.04). Only pain outcomes were considered clinically significant. Studies were limited to the short-term effects of pulsed electromagnetic field therapy, with study follow-up durations ranging from 10 days to 12 weeks.

A systematic review by Negm et al (2013), which included 7 small, sham-controlled randomized trials (N=459 patients), examined pulsed electrical stimulation and pulsed electromagnetic field for the treatment of knee osteoarthritis. The trials were published between 1994 and 2011, 5 were conducted outside of the United States and only the trial by Fary et al (2011), was considered to be at low-risk of bias. There was no significant difference between the active and sham groups for the outcome of pain. Physical function was significantly improved with pulsed electrical stimulation and pulsed electromagnetic field, with a SMD of 0.22. The internal validity of the selected studies was limited, including a high-risk of bias, inconsistent results, and imprecise estimates of treatment effect (wide CIs around estimates) due to small sample sizes.

A 2013 Cochrane review of pulsed electrical stimulation and pulsed electromagnetic field included 9 studies (N=636 patients) published between 1993 and 2013. Meta-analysis found that patients randomized to pulsed electrical stimulation or pulsed electromagnetic field rated their pain relief as better than sham-treated patients by 15.10 points more (95% CI 9.08 to 21.13; absolute improvement, 15%) on a scale of 0 to 100 but found no statistically significant effect for function or quality of life. There was a high-risk of bias due to incomplete outcome data in 3 studies. For all 9 studies, there were inadequacies in reporting of study designs and trial conduct, making it unclear whether there were selective outcomes reporting bias.

A number of the trials included in these meta-analyses are described briefly in the pulsed electrical stimulation and pulsed electromagnetic stimulation sections below.

Subsection Summary: Electrical Versus Electromagnetic Stimulation
Results from 3 systematic reviews reached somewhat different conclusions on the use of electrical and electromagnetic field stimulation for treating knee osteoarthritis. There was no significant difference between active and sham groups for at least 1 outcome of interest in all reviews. Studies had a high-risk of bias as well as inadequacies in reporting and validity. Overall, the evidence is insufficient that use of electrical stimulation therapies improves health outcomes.

Pulsed Electrical Stimulation
Randomized Controlled Trials
Fary et al (2011) reported on results from a randomized, double-blind, sham-controlled trial of pulsed electrical stimulation in 70 patients with osteoarthritis of the knee. The device used in this study was a commercially available transcutaneous electrical nerve stimulation unit (Metron Digi-10s) modified to provide pulsed electrical stimulation. In the placebo group, the device
tured itself off after 3 minutes. There were no statistically significant differences between the
groups in terms of pain, Western Ontario and McMaster University Arthritis Index (WOMAC)
scores, or 36-Item Short-Form Health Survey scores.

Garland et al (2007) reported on a randomized, double-blind, sham-controlled study of the
BioniCare device for 58 patients with osteoarthritis of the knee. Due to protocol violations from 1
of the centers (other new treatments were provided during the study), 42 subjects were
excluded from the analysis. At the end of 3 months of use, improvements in pain and WOMAC
scores were statistically significantly greater in the active device group than in the sham group.

In their pivotal study, Zizic et al (1995) reported on a multicenter, double-blind, randomized,
sham-controlled trial of pulsed electrical stimulation to assess pain relief and functional
improvements in 78 patients with osteoarthritis of the knee. Patients in the treatment group used
the BioniCare device and the placebo group used a dummy device that initially produced a
sensation like that of the BioniCare device. Both patient groups were instructed to dial down the
level to just below the sensation threshold. In the placebo group, the device would soon turn
itself off. The primary outcomes assessed at baseline and after 4 weeks of treatment included
patient assessment of pain and function and physician global evaluation of the patient's
condition. Trialists reported the BioniCare group had a statistically significant improvement
(defined as improvement ≥50%) compared with the sham group for each of the primary
outcomes assessed.

Nonrandomized Controlled Trials
Mont et al (2006) reported on a nonrandomized study of pulsed electrical stimulation in 157
patients (recruited from 23 centers) with moderate-to-severe knee osteoarthritis who required
total knee arthroplasty. The time to total knee arthroplasty was compared with a matched
(age, sex, weight) historical control group of 101 knee osteoarthritis patients treated at 1 of the
centers. Analysis showed that 60% of patients in the electrical stimulation group had deferred
total knee arthroplasty at 4 years compared with 35% in the historical control group.
Interpretation was limited due to the potential for higher motivation to avoid total knee
arthroplasty in the subjects who participated.

Uncontrolled Trials
VQ OrthoCare (2006) published data on 288 patients with knee osteoarthritis treated with its
BioniCare device in an open-label prospective study. Study participants experienced
improvements in patient assessment of pain, global evaluation of disease activity, and physician
global evaluation of the patients' condition. In addition, 45.4% reduced their use of NSAIDs by
50% or more. However, this study did not include a randomized control group.

Subsection Summary: Pulsed Electrical Stimulation
Three RCTs evaluated pulsed electrical stimulation for pain relief and functional improvement in
osteoarthritis compared with a sham. Analysis marginally favored pulsed electrical stimulation
over placebo. A nonrandomized controlled trial compared time to requirement of total knee
arthroplasty in osteoarthritis patients who had received pulsed electrical stimulation compared
to an untreated historical control. Deferral of total knee arthroplasty in the intervention group
is difficult to interpret. One uncontrolled trial had promising results and reported patients with
osteoarthritis of the knee who were treated with the device had experienced improvements in
several clinical areas and reduced their use of NSAIDs by nearly 50%.

Pulsed Electromagnetic Field Stimulation
Pulsed Electromagnetic Field Stimulation Versus Sham Treatment

Randomized Controlled Trials
Bagnato et al (2016) reported on a double-blind, sham-controlled trial of 12 hours nightly
treatment with a wearable ActiPatch. Sixty-six patients with osteoarthritis were randomized
and 60 completed the trial. Patients in the treatment group showed statistically significant
improvements in pain, WOMAC scores, and the 36-Item Short-Form Health Survey physical scores.

Wuschech et al (2015) evaluated use of 10 minutes of daily treatment with the Magcell Arthro (Physiomed Elektromedizin) in a sham-controlled, double-blind, semi-randomized study with 57 patients with osteoarthritis. Due to efficacy at the interim analysis, only the first 26 patients were randomized. The remainder were assigned to the active treatment group, although patients and assessors remained blinded to treatment allocation. It is unclear whether this study was sufficiently powered because power analysis indicated that 28 patients would be needed per group. Statistically significant improvements in WOMAC scores were reported by the treatment group compared with the sham group.

Nelson et al (2013) reported on a randomized, double-blind, sham-controlled pilot study with the Palermo device in 34 patients with osteoarthritis. In addition to having knee pain with confirmed articular cartilage loss and an initial visual analog scale score of 4 or more, only patients who had at least 2 hours of daily standing activity in a physical occupation were included in the study. Using an intention-to-treat analysis with last observation carried forward, significant decreases in pain scores were seen at 14 and 42 days. By 6 months, the maximum recorded visual analog scale score decreased by 39% in patients in the active treatment and by 15% in the sham group. The difference in visual analog scale scores between groups (4.19 for pulsed electromagnetic field vs. 6.11 for sham) was statistically and clinically significant. No additional studies with this device have been identified.

Fukuda et al (2011) reported on a double-blind RCT from South America that included 121 women with osteoarthritis divided into 4 groups: low (19-minute treatment) or high-dose (38-minute treatment) short-wave electrical field stimulation with a Diatermed II (9 sessions over 3 weeks), placebo, or no treatment control. Except for the untreated controls, both patients and the physical therapist evaluator were blinded throughout the 1-year follow-up. When measured immediately after treatment, both the low- and high-dose groups showed significantly greater improvement than the control groups in the numeric rating scale and the Knee Osteoarthritis Outcome Score subscales. The percentages of patients who attained the minimal clinically important difference of 2 points on the numeric rating scale were 15% in the control group, 15% in the placebo group, 75% in the low-dose group, and 50% in the high-dose group. At the 1-year follow-up, larger improvements in the Knee Osteoarthritis Outcome Score subscales were maintained by patients in the pulsed electromagnetic field groups. Because there was a 36% dropout rate (from patients lost to follow-up, patients who received other therapies, patients who had total knee replacement), analyses were performed both per-protocol and by last observation carried forward; these analyses yielded similar results.

Pulsed Electromagnetic Field Stimulation Plus Physical Therapy Versus Sham Pulsed Electromagnetic Field Stimulation

Randomized Controlled Trials

De Paula Gomes et al (2020) conducted a prospective, randomized, sham-controlled trial evaluating the effects of an exercise program alone or combined with electrophysical modalities in patients with knee osteoarthritis (N=100 patients). Patients were equally allocated into 5 groups (n=20): exercise, exercise + sham, exercise + interferential current therapy (ICT), exercise + pulsed shortwave diathermy therapy (SDT), and exercise + photobiomodulation. Patients received treatment 3 times weekly for a duration of 8 weeks. A significant improvement in WOMAC function and pain scores was observed in the exercise only group compared to all other groups, including SDT. The addition of ICT, SDT, or photobiomodulation did not result in any clinically meaningful benefits. No long-term follow-up assessments were performed after the 8 week treatment period and use of analgesics was not controlled in the study.

Dundar et al (2016) reported on a double-blind, sham-controlled randomized trial of 40 patients with knee osteoarthritis that evaluated 20 minutes of pulsed electromagnetic field (PMT Quattro...
Electrical and Electromagnetic Stimulation for the Treatment of Arthritis

1.01.27

PRO; ASA) plus 1 hour of physical therapy (including hot pack, ultrasound, transcutaneous nerve stimulation, and isometric knee exercise), and 20 minutes of sham pulsed electromagnetic field plus 1 hour of the same physical therapy regimen. Both groups—pulsed electromagnetic field plus physical therapy and sham pulsed electromagnetic field plus physical therapy—showed equally significant reductions in pain scores.

Ozguclu et al (2010) reported a double-blind RCT from Turkey investigating the effect of pulsed electromagnetic field plus physical therapy in 40 patients with knee osteoarthritis. Patients with an average pain intensity of 40 or more on a 100-mm visual analog scale were randomized to pulsed electromagnetic field plus physical therapy or to sham pulsed electromagnetic field plus physical therapy. Sessions included a 20-minute hot pack application, 5-minute ultrasound application, and 30 minutes of active or sham pulsed electromagnetic field 5 times a week for 2 weeks, along with isometric knee exercises performed at home. After 2 weeks, both groups showed reductions in pain and improvements in function scores on the WOMAC, but between-group differences were not statistically significant.

Subsection Summary: Pulsed Electromagnetic Field Stimulation

Studies comparing pulsed electromagnetic field with sham treatment showed benefits to the pulsed electromagnetic field devices; however, different devices were used in each trial, and 3 of the 4 trials were not conducted in the United States. The results from both randomized trials investigating the effect of pulsed electromagnetic field plus physical therapy on patients with osteoarthritis of the knee found that pulsed electromagnetic field as an adjuvant had no incremental benefit for reduction in pain or statistically significant benefit in stiffness and disability in patients. Both studies had short follow-up windows and long-term benefit of continued therapy cannot be ascertained at this time. Studies with longer periods of follow-up are needed to evaluate the efficacy of pulsed electromagnetic field therapy for osteoarthritis of the knee.

Summary of Evidence

For individuals who have arthritis who receive pulsed electrical or electromagnetic stimulation, the evidence includes a number of small RCTs. Relevant outcomes are symptoms, functional outcomes, health status measures, and treatment-related morbidity. A review of the literature did not find adequate evidence that use of pulsed electrical or electromagnetic stimulation for the treatment of arthritis improves health outcomes. A 2020 meta-analysis identified 15 randomized sham-controlled trials on treatment of osteoarthritis of the knee. There was some evidence of clinically and statistically significant improvement in pain, but no evidence of clinically significant improvement in stiffness, function, or quality of life. These conclusions are limited by methodologic shortcomings and inconsistent trial results. More recent RCTs have also had variable results, which might be related to the different devices and treatment durations used. Additional studies with larger numbers of subjects are needed. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

Supplemental Information

The purpose of the following information is to provide reference material. Inclusion does not imply endorsement or alignment with the evidence review conclusions.

Practice Guidelines and Position Statements

Guidelines or position statements will be considered for inclusion in ‘Supplemental Information’ if they were issued by, or jointly by, a US professional society, an international society with US representation, or National Institute for Health and Care Excellence (NICE). Priority will be given to guidelines that are informed by a systematic review, include strength of evidence ratings, and include a description of management of conflict of interest.

Osteoarthritis Research Society International

In 2019, the Osteoarthritis Research Society International published updated evidence-based consensus guidelines for the nonsurgical management of knee, hip, and polyarticular osteoarthritis. Sixty treatment modalities were evaluated for 3 patient groups: knee-only, hip,
and multijoint osteoarthritis. Neuromuscular electrical stimulation was considered "strongly recommended against" for all groups due to low quality evidence from trials with small sample sizes and insufficient duration of follow-up. Electromagnetic therapy was considered "strongly recommended against" for all groups due to low quality evidence and an implausible biological mechanism.

American Academy of Orthopaedic Surgeons
In 2013, the American Academy of Orthopaedic Surgeons published guidelines on the treatment of osteoarthritis of the knee. Due to the overall inconsistent finding for electrotherapeutic modalities, the American Academy of Orthopaedic Surgeons did not recommend for or against use in patients with symptomatic knee osteoarthritis. The strength of the recommendation was inconclusive.

American College of Rheumatology
In 2019, the American College of Rheumatology released guidelines for the management of osteoarthritis of the hand, hip, and knee. The guidelines do not mention pulsed electrical or electromagnetic stimulation, but they recommend against transcutaneous electrical stimulation for patients with knee and/or hip osteoarthritis.

In 2015, the American College of Rheumatology released recommendations for the treatment of rheumatoid arthritis. All recommended treatments were pharmacologic. Use of electrical stimulation for treating rheumatoid arthritis was not addressed. Updated 2020 guidelines are expected to be published in Spring 2021.

U.S. Preventive Services Task Force Recommendations
Not applicable.

Medicare National Coverage
There is no national coverage determination. In the absence of a national coverage determination, coverage decisions are left to the discretion of local Medicare carriers.

Ongoing and Unpublished Clinical Trials
Currently ongoing and unpublished trials that may influence this review are listed in Table 1.

**Definitions of Decision Determinations**

**Medically Necessary:** Services that are Medically Necessary include only those which have been established as safe and effective, are furnished under generally accepted professional standards to treat illness, injury or medical condition, and which, as determined by Blue Shield,
are: (a) consistent with Blue Shield medical policy; (b) consistent with the symptoms or diagnosis; (c) not furnished primarily for the convenience of the patient, the attending Physician or other provider; (d) furnished at the most appropriate level which can be provided safely and effectively to the patient; and (e) not more costly than an alternative service or sequence of services at least as likely to produce equivalent therapeutic or diagnostic results as to the diagnosis or treatment of the Member's illness, injury, or disease.

**Investigational/Experimental:** A treatment, procedure, or drug is investigational when it has not been recognized as safe and effective for use in treating the particular condition in accordance with generally accepted professional medical standards. This includes services where approval by the federal or state governmental is required prior to use, but has not yet been granted.

**Split Evaluation:** Blue Shield of California/Blue Shield of California Life & Health Insurance Company (Blue Shield) policy review can result in a split evaluation, where a treatment, procedure, or drug will be considered to be investigational for certain indications or conditions, but will be deemed safe and effective for other indications or conditions, and therefore potentially medically necessary in those instances.

### Prior Authorization Requirements (as applicable to your plan)

Within five days before the actual date of service, the provider must confirm with Blue Shield that the member's health plan coverage is still in effect. Blue Shield reserves the right to revoke an authorization prior to services being rendered based on cancellation of the member's eligibility. Final determination of benefits will be made after review of the claim for limitations or exclusions.

Questions regarding the applicability of this policy should be directed to the Prior Authorization Department at (800) 541-6652, or the Transplant Case Management Department at (800) 637-2066 ext. 3507708 or visit the provider portal at www.blueshieldca.com/provider.

**Disclaimer:** This medical policy is a guide in evaluating the medical necessity of a particular service or treatment. Blue Shield of California may consider published peer-reviewed scientific literature, national guidelines, and local standards of practice in developing its medical policy. Federal and state law, as well as contract language, including definitions and specific contract provisions/exclusions, take precedence over medical policy and must be considered first in determining covered services. Member contracts may differ in their benefits. Blue Shield reserves the right to review and update policies as appropriate.
