**Policy Statement**

The use of all forms of thermography is considered **investigational**.

**Policy Guidelines**

There is no specific code for skin surface infrared thermography.

These services are reported using the following unlisted code:
- **93799**: Unlisted cardiovascular service or procedure

The following CPT code is specific for temperature gradient studies:
- **93740**: Temperature gradient studies

**Description**

Thermography is a noninvasive imaging technique that measures temperature distribution in organs and tissues. The visual display of this temperature information is known as a thermogram. Thermography has been proposed as a diagnostic tool for treatment planning and for evaluation of treatment effects for a variety of conditions.

**Related Policies**

- Cardiac Applications of Positron Emission Tomography Scanning
- Interim Positron Emission Tomography Scanning in Oncology to Detect Early Response During Treatment
- Magnetic Resonance Imaging for Detection and Diagnosis of Breast Cancer
- Miscellaneous (Noncardiac, Nononcologic) Applications of Fluorine 18 Fluorodeoxyglucose Positron Emission Tomography
- Oncologic Applications of Positron Emission Tomography Scanning
- Positron Emission Mammography
- Scintimammography and Gamma Imaging of the Breast and Axilla
- Temporomandibular Joint Disorder

**Benefit Application**

Benefit determinations should be based in all cases on the applicable contract language. To the extent there are any conflicts between these guidelines and the contract language, the contract language will control. Please refer to the member's contract benefits in effect at the time of service to determine coverage or non-coverage of these services as it applies to an individual member.

Some state or federal mandates (e.g., Federal Employee Program [FEP]) prohibits plans from denying Food and Drug Administration (FDA)-approved technologies as investigational. In these instances, plans may have to consider the coverage eligibility of FDA-approved technologies on the basis of medical necessity alone.
### Regulatory Status

A number of thermographic devices have been cleared for marketing by the Food and Drug Administration through the 510(k) process. Food and Drug Administration product codes: LHQ, FXN. Devices with product code LHQ may only be marketed for adjunct use. Devices with product code FXN do not provide a diagnosis or therapy. Examples of these devices are shown in Table 1.

### Rationale

**Background**

Interpretation of the color patterns is thought to assist in the diagnosis of many disorders such as complex regional pain syndrome (previously known as reflex sympathetic dystrophy), breast cancer, Raynaud phenomenon, digital artery vasospasm in hand-arm vibration syndrome, peripheral nerve damage following trauma, impaired spermatogenesis in infertile men, degree of burns, deep vein thrombosis, gastric cancer, tear-film layer stability in dry-eye syndrome, Frey syndrome, headaches, lower back pain, and vertebral subluxation.

Infrared radiation from the skin or organ tissue reveals temperature variations by producing brightly colored patterns on a liquid crystal display. Thermography involves the use of an infrared scanning device and can include various types of telethermographic infrared detector images and heat-sensitive cholesteric liquid crystal systems.

Thermography may also assist in treatment planning and procedure guidance by accomplishing the following tasks: identifying restricted areas of perfusion in coronary artery bypass grafting, identifying unstable atherosclerotic plaques, assessing response to methylprednisolone in rheumatoid arthritis, and locating high undescended testicles.

**Literature Review**

Evidence reviews assess whether a medical test is clinically useful. A useful test provides information to make a clinical management decision that improves the net health outcome. That is, the balance of benefits and harms is better when the test is used to manage the condition than when another test or no test is used to manage the condition.

The first step in assessing a medical test is to formulate the clinical context and purpose of the test. The test must be technically reliable, clinically valid, and clinically useful for that purpose. Evidence reviews assess the evidence on whether a test is clinically valid and clinically useful. Technical reliability is outside the scope of these reviews, and credible information on technical reliability is available from other sources.

**Breast Cancer**

**Clinical Context and Test Purpose**

The purpose of using thermography in patients who are suspected of having breast cancer is to inform a decision whether to proceed to appropriate treatment or not.
The question addressed in this portion of the evidence review is: Does thermography when used to screen or diagnose breast cancer improve the net health outcome compared with standard mammographic techniques? Specifically, does the use of thermography improve diagnostic accuracy compared with standard screening mammography methods and is this increase in accuracy likely to improve health outcomes by leading to earlier diagnosis and treatment?

The following PICOs were used to select literature to inform this review.

**Patients**
The relevant populations of interest are asymptomatic individuals being screened for breast cancer or individuals undergoing testing to diagnose breast cancer.

**Interventions**
The intervention of interest is thermography. The test would be performed in an outpatient setting.

**Comparators**
The following test is currently being used to make decisions about breast cancer diagnosis: mammography.

**Outcomes**
The outcome of interest for diagnostic accuracy is test validity (i.e., sensitivity, specificity). The primary outcomes of interest for clinical utility are overall survival and breast cancer-specific survival rates.

The potential beneficial outcomes of primary interest in the case of a true-negative would be the avoidance of unnecessary surgery and its associated consequences (e.g., morbidity, mortality, resource utilization, patient anxiety). The potential harms from a false-positive could be inappropriate assessment and improper management of patients with breast malignancies, which could result in the following: inappropriate surgical decisions, high frequency of unnecessary further testing, and unnecessary patient anxiety. The potential harms from a false-negative could be a determination that the patient does not have malignancy, which would lead to a delay in surgery and tumor diagnosis.

The timing for routine screening can be guided by national guidelines on breast cancer screening. The timing for diagnosis would be after an initial screening test or clinical examination.

**Technically Reliable**
Assessment of technical reliability focuses on specific tests and operators and requires a review of unpublished and often proprietary information. Review of specific tests, operators, and unpublished data are outside the scope of this evidence review and alternative sources exist. This evidence review focuses on the clinical validity and clinical utility.

**Clinically Valid**
A test must detect the presence or absence of a condition, the risk of developing a condition in the future, or treatment response (beneficial or adverse).

**Systematic Reviews**
Several systematic reviews of the published literature on the diagnostic accuracy of thermography were identified. A systematic review by Vreugdenburg et al (2013) identified 8 studies on thermography for diagnosis of breast cancer that included a valid reference standard (e.g., biopsy with histopathologic confirmation). A previous systematic review by Fitzgerald and Berentson-Shaw (2012) identified 6 studies, one using thermography for breast cancer screening and the others using thermography to diagnose breast cancer among symptomatic women or those with a positive mammogram. A summary of the characteristics of clinical validity for these systematic reviews is provided in Table 2. A summary of the clinical
validity results is provided in Table 3. Study findings were not pooled due to heterogeneity in data reporting and assessment methodology utilized.

Several studies have been published since the systematic reviews. Morales-Cervantes et al (2018) compared the accuracy of automated or manual thermography screening in 206 women scheduled for mammography in Mexico. A retrospective study conducted in the U.S. by Neal et al (2018) assessed outcomes in 38 women referred for further breast imaging following abnormal thermography testing. Omranipour et al (2016) compared the accuracy of thermography and mammography in 132 patients in Iran who had breast lesions and were candidates for breast biopsy. Rassiwala et al (2014) in India reported on 1008 women being screened for breast cancer. Summaries of characteristics and results of clinical validity for these diagnostic studies are provided in Tables 4 and 5.

³ Note 2 aspects of design: prospective, retrospective or nonconcurrent prospective; sample selection random or consecutive.

⁴ Note other characteristics that could bias or limit relevance such as use of historical data, evolution of technology, or practice setting.

⁵ Thermal score is defined as the sum of the surface temperature difference at the site of the lesion compared to that of the contralateral breast and the vascularity score, based on the following scale: 1) absence of vascular patterns; 2) symmetrical or moderate vascular patterns; 3) significant vascular asymmetry; 4) vascular asymmetry extended in at least one-third of breast area.

NA: not applicable; NPV: negative predictive value; NR: not reported; PPV: positive predictive value.

* Clinical validity results for this subgroup must be interpreted with caution as subjects with normal mammograms did not undergo histopathologic reference testing for diagnostic confirmation.

** Clinical validity results for this subgroup must be interpreted with caution as subjects with normal thermograms did not undergo radiologic and histopathologic reference testing for diagnostic confirmation, only clinical assessment.

The diagnostic accuracy of automated thermography in the study by Morales-Cervantes et al (2018) was 69.9%.3 The authors did not report on the diagnostic accuracy of manual thermography. While automated thermographic screening improved the sensitivity and specificity of the test compared to a manual, qualitative approach, reported values must be interpreted with caution as only patients with positive mammograms were subjected to diagnostic reference testing. Neal et al (2018) indicated that 95% of patients referred for follow-up imaging evaluation following abnormal thermography testing did not have breast cancer, concluding that conventional breast imaging appears sufficient to manage patients.4 According to Omranipour et al (2016),5 the diagnostic accuracy of thermography (67.7%) was lower than for mammography (76.9% p-values not reported). The reported false-negative rate was not accurately calculated in Rassiwala et al (2014) because women who had normal thermograms only had a clinical examination and did not undergo radiologic and histopathologic reference tests for confirmation, highlighting a major limitation of this study. For patients with positive or abnormal thermograms, eight results were considered false-positive. One false-negative was reported but it is unclear which subgroup this patient belonged to or how this was determined, given that patients with normal thermograms were only assessed with a clinical examination. Limitations tables (see Tables 6 and 7) display further notable limitations identified in each study. This information is synthesized as a summary of the body of evidence following each table and provides the conclusions on the sufficiency of the evidence supporting the position statement.

The study limitations stated in this table are those notable in the current review; this is not a comprehensive limitations assessment.

BI-RADS: breast imaging reporting and data system.

**Population Key**: 1. Intended use population unclear; 2. Clinical context is unclear; 3. Study population is unclear; 4. Study population not representative of intended use.

**Intervention Key**: 1. Classification thresholds not defined; 2. Version used unclear; 3. Not intervention of interest.

**Comparator Key**: 1. Classification thresholds not defined; 2. Not compared to credible reference standard; 3. Not compared to other tests in use for same purpose.

**Outcomes Key**: 1. Study does not directly assess a key health outcome; 2. Evidence chain or decision model not explicated; 3. Key clinical validity outcomes not reported (sensitivity, specificity and predictive values); 4. Reclassification of diagnostic or risk categories not reported; 5. Adverse events of the test not described (excluding minor discomforts and inconvenience of venipuncture or noninvasive tests).

**Follow-Up Key**: 1. Follow-up duration not sufficient with respect to natural history of disease (true positives, true negatives, false positives, false negatives cannot be determined).
### Clinical Usefulness

A test is clinically useful if the use of the results informs management decisions that improve the net health outcome of care. The net health outcome can be improved if patients receive correct therapy, or more effective therapy, or avoid unnecessary therapy, or avoid unnecessary testing.

#### Direct Evidence

Direct evidence of clinical utility is provided by studies that have compared health outcomes for patients managed with and without the test. Because these are intervention studies, the preferred evidence would be from randomized controlled trials.

No studies have demonstrated how the results of thermography could be used to enhance the management of breast cancer patients in a manner that would improve their health outcomes.

#### Chain of Evidence

Indirect evidence on clinical utility rests on clinical validity. If the evidence is insufficient to demonstrate test performance, no inferences can be made about clinical utility.

It is not possible to construct a chain of evidence for clinical utility due to the lack of sufficient evidence that the diagnostic accuracy of thermography is at least as high as mammographic techniques for breast cancer screening and diagnosis.

### Section Summary: Breast Cancer

Systematic reviews of studies evaluating the accuracy of thermography for diagnosing breast cancer found wide ranges of sensitivities and specificities and, where data are available, relatively low diagnostic accuracy compared with mammography. To date, no study has demonstrated that thermography is sufficiently accurate to replace or supplement mammography for breast cancer diagnosis. Moreover, there are no studies on the impact of thermography on patient management or health outcomes for patients with breast cancer.

### Musculoskeletal Injuries

#### Clinical Context and Test Purpose

The purpose of using thermography in patients who have a musculoskeletal injury is to inform a decision whether to proceed to appropriate treatment or not.

### Study Selection

<table>

<td>or missing samples.</td>
<td>p values not reported.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The question addressed in this portion of the evidence review is: Does thermography when used to diagnose musculoskeletal injuries, improve the net health outcome compared with standard approaches. Specifically, does the use of thermography improve diagnostic accuracy compared with standard approaches (e.g., clinical examination, imaging with radiography or magnetic resonance imaging), and is this degree of increased accuracy likely to improve health outcomes by leading to earlier diagnosis and treatment?

The following PICOs were used to select literature to inform this review.

**Patients**
The relevant population of interest are individuals with musculoskeletal pain.

**Interventions**
The intervention of interest is thermography. The test would be performed in an outpatient setting.

**Comparators**
The following tests and practices are currently being used to make decisions about musculoskeletal injuries: standard care without imaging and other forms of imaging (e.g., with radiography, magnetic resonance imaging).

**Outcomes**
The outcomes of interest for diagnostic accuracy include test accuracy and test validity (i.e., sensitivity, specificity). The primary outcomes of interest for clinical utility are a reduction in pain symptoms and improvement in functional ability. The timing would be following a musculoskeletal injury.

**Technically Reliable**
Assessment of technical reliability focuses on specific tests and operators and requires a review of unpublished and often proprietary information. Review of specific tests, operators, and unpublished data are outside the scope of this evidence review and alternative sources exist. This evidence review focuses on the clinical validity and clinical utility.

**Clinically Valid**
A test must detect the presence or absence of a condition, the risk of developing a condition in the future, or treatment response (beneficial or adverse).

**Systematic Reviews**
A systematic review by Sanchis-Sanchez et al (2014) evaluated the literature on thermography for diagnosing musculoskeletal injuries. Six studies met the eligibility criteria (n=416); 3 included patients with suspected stress fractures (n=119) and the remainder addressed other musculoskeletal injuries. Characteristics and results of clinical validity for stress fracture diagnostic studies were reported and summaries are provided in Tables 8 and 9. A systematic review by Vardasca et al (2019) evaluated the literature on musculoskeletal applications of thermography specific to the arm and forearm. However, the review mainly focused on correlations between skin surface temperatures and physical condition or health recovery monitoring. As diagnostic accuracy data was not extracted or pooled from included studies, this review was not assessed for evidence of clinical validity.

Clinically Useful
A test is clinically useful if the use of the results informs management decisions that improve the net health outcome of care. The net health outcome can be improved if patients receive correct therapy, or more effective therapy, or avoid unnecessary therapy, or avoid unnecessary testing.

Direct Evidence
Direct evidence of clinical utility is provided by studies that have compared health outcomes for patients managed with and without the test. Because these are intervention studies, the preferred evidence would be from randomized controlled trials.
Longitudinal Studies
Côrte et al (2019) published pilot data from a longitudinal prospective study on the screening and prevention of muscle injuries in 28 professional Brazilian soccer players. Players were monitored for musculoskeletal imaging during the 2015-2016 seasons with ultrasound. In the second season, a thermographic monitoring regimen was added twice-weekly 48 hours after matches, and an injury prevention protocol was followed based on the results of thermographic imaging. The number of musculoskeletal injuries was compared for both seasons based on these management protocols. The total number of muscle injuries reported decreased from 11 in 2015 to 4 in 2016 (p=0.04). Seven players were on the team roster across both seasons. There was no statistically significant reduction in muscle injury in this subgroup (p=0.06). Limitations of this study are addressed in Tables 10 and 11.

The study limitations stated in this table are those notable in the current review; this is not a comprehensive limitations assessment.

² Selection key: 1. Selection not described; 2. Selection not random or consecutive (i.e., convenience).
³ Blinding key: 1. Not blinded to results of reference or other comparator tests.
⁴ Test Delivery key: 1. Timing of delivery of index or reference test not described; 2. Timing of index and comparator tests not same; 3. Procedure for interpreting tests not described; 4. Expertise of evaluators not described.
No high-quality or randomized studies have been published that evaluate health outcomes in patients with musculoskeletal injuries who were managed with and without thermography.

**Chain of Evidence**
Indirect evidence on clinical utility rests on clinical validity. If the evidence is insufficient to demonstrate test performance, no inferences can be made about clinical utility.

It is not possible to construct a chain of evidence for clinical utility due to the lack of sufficient evidence that the diagnostic accuracy of thermography is at least as high as standard techniques for diagnosing musculoskeletal injuries.

**Section Summary: Musculoskeletal Injuries**
A systematic review of studies on thermography for diagnosing musculoskeletal injuries found moderate levels of accuracy compared with other diagnostic imaging tests. There was a lack of a consistent reference standard. This evidence does not permit conclusions as to whether thermography is sufficiently accurate to replace or supplement standard testing. Moreover, there are insufficient studies on the impact of thermography on patient management or health outcomes for patients with musculoskeletal injuries.

**Temporomandibular Joint Disorder**

**Clinical Context and Test Purpose**
The purpose of using thermography in patients who have TMJ disorder is to inform a decision whether to proceed to appropriate treatment or not.

The question addressed in this portion of the evidence review is: Does thermography when used to diagnose TMJ disorder, improve the net health outcome compared with standard approaches. Specifically, does the use of thermography improve diagnostic accuracy compared with standard approaches (e.g., clinical examination, imaging with radiography or magnetic resonance imaging), and is this degree of increased accuracy likely to improve health outcomes by leading to earlier diagnosis and treatment?

The following PICOs were used to select literature to inform this review.

**Patients**
The relevant population of interest are individuals with TMJ pain.

**Interventions**
The intervention of interest is thermography. The test would be performed in an outpatient setting.

**Comparators**
The following tests and practices are currently being used to make decisions about TMJ disorder: standard clinical examination without imaging, diagnostic scales (e.g., Research Diagnostic Criteria for Temporomandibular Disorders [RDC/TMD], Fonseca Anamnestic Index, Anamnestic Index), and other forms of imaging (e.g., with radiography, arthrotomography, magnetic resonance imaging).

**Outcomes**
The outcomes of interest for diagnostic accuracy include test accuracy and test validity (i.e., sensitivity, specificity). The primary outcomes of interest for clinical utility are a reduction in pain symptoms and improvement in functional ability.
Technically Reliable

Assessment of technical reliability focuses on specific tests and operators and requires a review of unpublished and often proprietary information. Review of specific tests, operators, and unpublished data are outside the scope of this evidence review and alternative sources exist. This evidence review focuses on the clinical validity and clinical utility.

Clinically Valid

A test must detect the presence or absence of a condition, the risk of developing a condition in the future, or treatment response (beneficial or adverse).

Systematic Reviews

A systematic review by de Melo et al (2019) evaluated the diagnostic accuracy of infrared thermography in TMJ disorder. Nine studies were identified utilizing a variety of comparators. The authors note that while no specific diagnostic tool is currently considered the gold standard for the diagnosis of TMJ disorder, the RDC/TMD diagnostic is commonly used with a reported sensitivity and specificity of 87% and 92% respectively. Four out of nine studies utilized RDC/TMD, whereas the remaining studies utilized clinical examination or other methods. Characteristics and results of clinical validity for temporomandibular joint disorder diagnostic accuracy in this systematic review are summarized in Tables 12 and 13.

Clinically Useful

A test is clinically useful if the use of the results informs management decisions that improve the net health outcome of care. The net health outcome can be improved if patients receive correct therapy, or more effective therapy, or avoid unnecessary therapy, or avoid unnecessary testing.
Direct Evidence
Direct evidence of clinical utility is provided by studies that have compared health outcomes for patients managed with and without the test. Because these are intervention studies, the preferred evidence would be from randomized controlled trials.

No studies have been published that evaluate health outcomes in patients with TMJ disorder who were managed with and without thermography.

Chain of Evidence
Indirect evidence on clinical utility rests on clinical validity. If the evidence is insufficient to demonstrate test performance, no inferences can be made about clinical utility.

It is not possible to construct a chain of evidence for clinical utility due to the lack of sufficient evidence that the diagnostic accuracy of thermography is at least as high as standard techniques for diagnosing TMJ disorder.

Section Summary: TMJ Disorder
A systematic review of studies on thermography for diagnosing TMJ disorder found a wide variation in accuracy compared with other diagnostics. There was a lack of a consistent reference standard. This evidence does not permit conclusions as to whether thermography is sufficiently accurate to replace or supplement standard testing. Moreover, there are no studies on the impact of thermography on patient management or health outcomes for patients with TMJ disorder.

Miscellaneous Conditions
A number of studies have assessed a range of potential thermography applications. To date, no randomized study has examined the impact of thermography on patient management decisions or health outcomes. Examples of other studies on thermography, mainly conducted outside of the U.S., include those evaluating the association between thermographic findings and post-herpetic neuralgia in patients with herpes zoster,10,11, surgical site healing in patients who underwent knee replacements,12, predicting pressure ulcers13, and pressure ulcer healing,14, posttreatment pain in patients with coccygodynia,15, evaluation of allergic conjunctivitis,16, evaluation of bum depth17, and a association between thermographic findings and bum treatment;18, detecting cervical lymph node metastasis from oral cavity cancer,19, monitoring lesions or inflammation in patients with scleroderma,20,21, detection of vascular obstruction22, or perforator vessels during surgery,23,24, diagnosis of lower extremity cellulitis,25, prediction of infrainguinal bypass surgery,26, detection of melanoma,27, detection of contact dermatitis during allergy patch testing,28, and measuring disease activity in patients with rheumatoid arthritis.29

Several studies evaluating the clinical validity of thermography to assess potential complications of the diabetic foot have been conducted. Thermographic images of nondiabetic feet, nonulcerated diabetic feet and ulcerated diabetic feet have been compared.30-33 Another study used thermography to diagnose infections in patients admitted with diabetic foot complications.34 While these studies reported temperature differences between the different feet, none investigated clinical utility, in which health outcomes were compared in patients who were managed with and without thermography results.

Section Summary: Miscellaneous Conditions
For most of these potential indications, there are one or two preliminary studies on each of the indications. Several studies evaluated the clinical validity of thermography in assessing diabetic foot and related complications. For all indications, the studies described temperature gradients or the association between temperature differences and the clinical condition. Due to the small number of studies for each indication, the diagnostic accuracy could not adequately be evaluated. The clinical utility of thermography for these miscellaneous conditions was not investigated in any study.
Summary of Evidence
For individuals who have an indication for breast cancer screening or diagnosis who receive thermography, the evidence includes diagnostic accuracy studies and systematic reviews. The relevant outcomes are overall survival, disease-specific survival, and test validity. Using histopathologic findings as the reference standard, a series of systematic reviews of studies have evaluated the accuracy of thermography to screen and/or diagnose breast cancer and reported wide ranges of sensitivities and specificities. To date, no study has demonstrated whether thermography is sufficiently accurate to replace or supplement mammography for breast cancer diagnosis. Moreover, there are no studies on the impact of thermography on patient management or health outcomes for patients with breast cancer. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals who have musculoskeletal injuries who receive thermography, the evidence includes diagnostic accuracy studies, a longitudinal prospective study, and a systematic review. The relevant outcomes are test validity, symptoms, and functional outcomes. A systematic review of studies on thermography for diagnosing musculoskeletal injuries found moderate levels of accuracy compared with other diagnostic imaging tests. There is a lack of a consistent reference standard. This evidence does not permit conclusions as to whether thermography is sufficiently accurate to replace or supplement standard testing. Moreover, there are no high-quality or randomized studies on the impact of thermography on patient management or health outcomes for patients with musculoskeletal injuries. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals who have TMJ disorder who receive thermography, the evidence includes a systematic review. The relevant outcomes are test validity, symptoms, and functional outcomes. A systematic review of studies on thermography for diagnosing TMJ disorder found a wide variation in accuracy compared to other diagnostics. There is a lack of a consistent reference standard. The evidence does not permit conclusions as to whether thermography is sufficiently accurate to replace or supplement standard testing. Moreover, there are no studies on the impact of thermography on patient management or health outcomes for patients with TMJ disorder. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals who have miscellaneous conditions (e.g., herpes zoster, pressure ulcers, diabetic foot) who receive thermography, the evidence includes diagnostic accuracy studies. The relevant outcomes are test validity, symptoms, and functional outcomes. There are one or two preliminary studies on each of these potential indications for thermography. Most studies assessed temperature gradients or the association between temperature differences and the clinical condition. Due to the small number of studies for each indication, diagnostic accuracy could not adequately be evaluated. The clinical utility of thermography for any of these miscellaneous conditions has not been investigated in studies considered. The evidence is insufficient to determine the effects of the technology on health outcomes.

Supplemental Information
Practice Guidelines and Position Statements

European Society of Breast Imaging
A position paper by the European Society of Breast Imaging (2017) and 30 other national breast radiology bodies on screening for breast cancer stated that “screening with thermography or other optical tools as alternatives to mammography is discouraged.”

American College of Physicians
The American College of Physicians (2019) issued a guidance statement for breast cancer screening in average-risk women that reviews existing screening guidelines. While the use of thermography was not mentioned in this statement, the authors conclude that evidence is
insufficient to understand the benefits and harms of primary or adjunctive screening strategies in women who are found to have dense breasts on screening mammography.\textsuperscript{36}.

**American College of Radiology**
The American College of Radiology guidelines for breast cancer screening (revised 2017) do not mention the use of thermography for breast cancer screening.\textsuperscript{37}.

**National Comprehensive Cancer Network**
National Comprehensive Cancer Network guidelines on breast cancer screening and diagnosis (v.1.2019) states that: “Current evidence does not support the routine use of thermography or ductal lavage as screening procedures.”\textsuperscript{38}.

**U.S. Preventive Services Task Force Recommendations**
The U.S. Preventive Services Task Force (2016) recommendations on breast cancer screening do not mention thermography. Additionally, there is insufficient evidence for the use of adjunctive screening methods for breast cancer (ultrasonography, magnetic resonance imaging, digital breast tomosynthesis, or other methods) in women identified to have dense breasts on a negative screening mammogram.\textsuperscript{39}.

**Medicare National Coverage**
Medicare does not cover thermography. Current Medicare coverage policy states: "Thermography for any indication (including breast lesions which were excluded from Medicare coverage...) is excluded from Medicare coverage because the available evidence does not support this test as a useful aid in the diagnosis or treatment of illness or injury. Therefore, it is not considered effective..."\textsuperscript{40}.

**Ongoing and Unpublished Clinical Trials**
Some currently ongoing and unpublished trials that might influence this review are listed in Table 14.

**Definitions of Decision Determinations**

**Medically Necessary:** A treatment, procedure, or drug is medically necessary only when it has been established as safe and effective for the particular symptoms or diagnosis, is not investigational or experimental, is not being provided primarily for the convenience of the patient or the provider, and is provided at the most appropriate level to treat the condition.

**Investigational/Experimental:** A treatment, procedure, or drug is investigational when it has not been recognized as safe and effective for use in treating the particular condition in accordance with generally accepted professional medical standards. This includes services where approval by the federal or state governmental is required prior to use, but has not yet been granted.

**Split Evaluation:** Blue Shield of California/Blue Shield of California Life & Health Insurance Company (Blue Shield) policy review can result in a split evaluation, where a treatment, procedure, or drug will be considered to be investigational for certain indications or conditions, but will be deemed safe and effective for other indications or conditions, and therefore potentially medically necessary in those instances.

**Prior Authorization Requirements (as applicable to your plan)**

Within five days before the actual date of service, the provider must confirm with Blue Shield that the member's health plan coverage is still in effect. Blue Shield reserves the right to revoke an authorization prior to services being rendered based on cancellation of the member's eligibility. Final determination of benefits will be made after review of the claim for limitations or exclusions.

Questions regarding the applicability of this policy should be directed to the Prior Authorization Department. Please call (800) 541-6652 or visit the provider portal at www.blueshieldca.com/provider.

Disclaimer: This medical policy is a guide in evaluating the medical necessity of a particular service or treatment. Blue Shield of California may consider published peer-reviewed scientific literature, national guidelines, and local standards of practice in developing its medical policy. Federal and state law, as well as contract language, including definitions and specific contract provisions/exclusions, take precedence over medical policy and must be considered first in determining covered services. Member contracts may differ in their benefits. Blue Shield reserves the right to review and update policies as appropriate.
