Policy Statement

Testing for BRAF V600 variants in tumor tissue of patients with unresectable or metastatic melanoma may be considered medically necessary to select patients for treatment with Food and Drug Administration-approved BRAF or MEK inhibitors.

Testing for BRAF V600 variants in tumor tissue of patients with resected stage III melanoma may be considered medically necessary to select patients for treatment with Food and Drug Administration-approved BRAF or MEK inhibitors.

Testing for BRAF V600 variants for all other patients with melanoma is considered investigational.

Testing for BRAF V600 variants in patients with glioma to select patients for targeted treatment is considered investigational.

Policy Guidelines

**Note:** This policy does not apply to BRAF testing related to colorectal cancer (see Blue Shield of California Medical Policies: Genetic Testing for Lynch Syndrome and Other Inherited Colon Cancer Syndromes and KRAS, NRAS, and BRAF Variant Analysis in Metastatic Colorectal Cancer).

**Genetics Nomenclature Update**

The Human Genome Variation Society (HGVS) nomenclature is used to report information on variants found in DNA and serves as an international standard in DNA diagnostics. It is being implemented for genetic testing medical evidence review updates starting in 2017 (see Table PG1). The Society’s nomenclature is recommended by the Human Variome Project, the Human Genome Organization, and by the Human Genome Variation Society itself.

The American College of Medical Genetics and Genomics (ACMG) and the Association for Molecular Pathology (AMP) standards and guidelines for interpretation of sequence variants represent expert opinion from both organizations, in addition to the College of American Pathologists. These recommendations primarily apply to genetic tests used in clinical laboratories, including genotyping, single genes, panels, exomes, and genomes. Table PG2 shows the recommended standard terminology—“pathogenic,” “likely pathogenic,” “uncertain significance,” “likely benign,” and “benign”—to describe variants identified that cause Mendelian disorders.

Likely benign | Likely benign change in the DNA sequence
Benign | Benign change in the DNA sequence

ACMG: American College of Medical Genetics and Genomics; AMP: Association for Molecular Pathology.

**Coding**

There is a specific CPT code for BRAF Gene Mutation Testing when used to select BRAF Inhibitor Targeted Therapy:

- **81210**: BRAF (B-Raf proto-oncogene, serine/threonine kinase) (e.g., colon cancer, melanoma), gene analysis, V600 variant(s)

**Description**

BRAF and MEK inhibitors are drugs designed to target a somatic variant in the BRAF gene. The inhibitors were originally developed for patients with advanced melanoma. BRAF encodes a kinase component in the RAF-MEK-ERK signal transduction phosphorylation cascade. Mutated BRAF causes constitutive kinase activity, which is believed to promote oncogenic proliferation. Direct and specific inhibition of the mutated kinase has been shown to retard tumor growth significantly and may improve patient survival.

**Related Policies**

- Genetic Testing for Lynch Syndrome and Other Inherited Colon Cancer Syndromes
- Molecular Analysis for Targeted Therapy of Non-Small-Cell Lung Cancer

**Benefit Application**

Benefit determinations should be based in all cases on the applicable contract language. To the extent there are any conflicts between these guidelines and the contract language, the contract language will control. Please refer to the member's contract benefits in effect at the time of service to determine coverage or non-coverage of these services as it applies to an individual member.

Some state or federal mandates (e.g., Federal Employee Program [FEP]) prohibits plans from denying Food and Drug Administration (FDA)-approved technologies as investigational. In these instances, plans may have to consider the coverage eligibility of FDA-approved technologies on the basis of medical necessity alone.

**Regulatory Status**

Table 1 summarizes the targeted treatments approved by the U.S. Food and Drug Administration for patients with melanoma along with the concurrently approved diagnostic tests. The combination agent encorafenib and binimetinib (Array BioPharma) is under review for the treatment of BRAF variant advanced, unresectable, or metastatic melanoma with target action date of June 30, 2018. The combination agent of dabrafenib and trametinib (GlaxoSmithKline) was approved in May 2018 for adjuvant treatment of BRAF variant, resected, stage III melanoma; the agent had both breakthrough therapy and priority review designations.

Rationale

Background Melanoma

Overall incidence rates for melanoma have been increasing for at least 30 years; in 2017, there were more than 87,100 new cases. In advanced (stage IV) melanoma, the disease has spread beyond the original area of skin and nearby lymph nodes. Although only a small proportion of cases are stage IV at diagnosis, the prognosis is extremely poor; 5-year survival is 15% to 20%.

Treatment Unresectable or Metastatic Melanoma

For several decades after its approval in 1975, cytotoxic chemotherapy with dacarbazine was considered the standard systemic therapy but has provided disappointingly low response rates of only 15% to 25% and median response duration of 5 to 6 months; less than 5% of responses are complete. Temozolomide has similar efficacy and, unlike dacarbazine, has much better efficacy with central nervous system tumors. Recently immunotherapy with ipilimumab or with checkpoint inhibitors such as pembrolizumab and nivolumab has demonstrated superior efficacy to chemotherapy regardless of BRAF status and is now recommended as a potential first-line treatment of metastatic or unresectable melanoma.

Variants in the BRAF kinase gene are common in tumors of patients with advanced melanoma and result in constitutive activation of a key signaling pathway (RAF-MEK-ERK pathway) that is associated with oncogenic proliferation. In general, 50% to 70% of melanoma tumors harbor a BRAF variant; of these, 80% are positive for the BRAF V600E variant, and 16% are positive for BRAF V600K. Thus, 45% to 60% of advanced melanoma patients may respond to a BRAF inhibitor targeted to this mutated kinase.
Two BRAF inhibitors (vemurafenib, dabrafenib) and 2 MEK inhibitors (trametinib, cobimetinib) have been developed for use in patients with advanced melanoma. Vemurafenib (also known as PLX4032 and RO5185426) was developed using a fragment-based, structure-guided approach that allowed the synthesis of a compound with high potency to inhibit the BRAF $V_{600E}$ mutated kinase and with significantly lower potency to inhibit most of many other kinases tested. Preclinical studies have demonstrated that vemurafenib selectively blocked the RAF-MEK-ERK pathway in BRAF mutant cells and caused regression of BRAF mutant human melanoma xenografts in murine models. Paradoxically, preclinical studies also showed that melanoma tumors with the BRAF wild-type gene sequence could respond to mutant BRAF-specific inhibitors with accelerated growth, suggesting that it may be harmful to administer BRAF inhibitors to patients with BRAF wild-type melanoma tumors. Potentiated growth in BRAF wild-type tumors has not yet been confirmed in melanoma patients, because the supportive clinical trials were enrichment trials, enrolling only patients with tumors positive for the BRAF $V_{600E}$ variant.

Dabrafenib (also known as GSK2118436 or SB-590885) inhibits several kinases, including mutated forms of the BRAF kinase, with the greatest activity against V600E-mutated BRAF. In vitro and in vivo studies have demonstrated dabrafenib’s ability to inhibit the growth of BRAF V600-variant melanoma cells.

Trametinib is an inhibitor of mitogen-activated extracellular signal-regulated kinase 1 (MEK1) and MEK2. MEK kinases regulate the extracellular signal-related kinase, which promotes cellular proliferation. BRAF $V_{600E}$ and $V_{600K}$ variants result in constitutive activation of MEK1 and MEK2. Trametinib inhibits the growth of BRAF V600 variant-positive melanoma cells in vitro and in vivo.

Cobimetinib is a MEK1 and MEK2 inhibitor. Coadministration of cobimetinib and vemurafenib has resulted in increased apoptosis and reduced tumor growth of BRAF V600E tumor cells in vitro, and cobimetinib has prevented the vemurafenib-mediated growth of a wild-type BRAF tumor cells in vivo.

Resected Stage III Melanoma
Wide local excision is the definitive surgical treatment of melanoma. Following surgery, patients with American Joint Committee on Cancer stage III melanoma may receive adjuvant therapy. Ipilimumab, a monoclonal antibody targeting cytotoxic T-lymphocyte antigen 4 (CTLA-4), has been shown to prolong recurrence-free survival by approximately 25% compared with placebo at a median of 5.3 years in patients who had resected stage III disease. Nivolumab, a programmed cell death protein 1 blocking antibody, has been shown to further prolong survival compared with ipilimumab by approximately 35% at 18 months. Before the development of checkpoint inhibitor immunotherapy and targeted therapy, high-dose interferon alfa was an option for adjuvant treatment of stage III melanoma. Interferon alfa has demonstrated an improvement in overall survival but with numerous serious side effects.

Glioma
More than 79,000 new cases of primary malignant and nonmalignant brain and other central nervous system tumors are expected to be diagnosed in the United States in 2017, the majority of which are gliomas. Gliomas encompass a heterogeneous group of tumors and classification of gliomas has changed over time. In 2016, the World Health Organization (WHO) updated its classification of gliomas based on both histopathologic appearance and molecular parameters. The classification ranges from grade I to IV, corresponding to the degree of malignancy (aggressiveness), with WHO grade I being least aggressive and grade IV being most aggressive.

Treatment
Low-grade gliomas are classified as WHO grade I or II and include pilocytic astrocytoma, diffuse astrocytoma, and oligodendroglioma. Surgical resection of the tumor is generally performed,
although additional therapy with radiotherapy and chemotherapy following surgery is usually required, except for pilocytic astrocytoma. The optimal timing of additional therapies is unclear. Many patients will recur following initial treatment, with a clinical course similar to high-grade glioma.

High-grade gliomas (WHO grade III/IV) include anaplastic gliomas and glioblastoma. Maximal surgical resection is the initial treatment followed by combined adjuvant chemoradiotherapy. Temozolomide, an oral alkylating agent, is considered standard systemic chemotherapy for malignant gliomas. The prognosis for patients with high-grade gliomas is poor; the 1-year survival in U.S. patients with anaplastic astrocytoma is about 63% and with glioblastoma is about 38%.

There is a high frequency of BRAF V600E variants in several types of gliomas. For example, BRAF V600E variants have been found in 5% to 10% of pediatric diffusely infiltrating gliomas, 10% to 15% of pilocytic astrocytoma, 20% of ganglioglioma, and more than 50% of pleomorphic xanthoastrocytoma. However, it may be rare in adult glioblastoma.

There is considerable interest in targeted therapies that inhibit the RAF-MEK-ERK pathway, particularly in patients with high-grade and low-grade gliomas whose tumors are in locations that prevent full resection. Evidence from early-phase trials in patients with BRAF variant-positive melanoma with brain metastases has suggested some efficacy for brain tumor response with vemurafenib and dabrafenib, indicating that these agents might be potential therapies for primary brain tumors.

**Literature Review**

Evidence reviews assess whether a medical test is clinically useful. A useful test provides information to make a clinical management decision that improves the net health outcome. That is, the balance of benefits and harms is better when the test is used to manage the condition than when another test or no test is used to manage the condition.

The first step in assessing a medical test is to formulate the clinical context and purpose of the test. The test must be technically reliable, clinically valid, and clinically useful for that purpose. Evidence reviews assess the evidence on whether a test is clinically valid and clinically useful. Technical reliability is outside the scope of these reviews, and credible information on technical reliability is available from other sources.

**Unresectable or metastatic Melanoma**

When treatment is developed for a specific biologic target that characterizes only some patients with a particular disease, and a test is codeveloped to identify diseased patients with that target, clinical validity and clinical utility cannot be evaluated separately. Rather, clinical studies of treatment benefit, which use the test to select patients, provide evidence of both clinical validity and clinical utility. We reviewed the phase 3 clinical trials of treatments in which testing for the BRAF variant was required for selection into the trial. In the absence of clinical trials in which both patients with and without BRAF variants are entered into RCTs of novel therapies, we cannot be certain that the test has clinical utility because it is unknown whether the treatment would be effective in patients without BRAF variant. However, patients without BRAF variants have not been enrolled in clinical trials of BRAF inhibitors.

**Clinical Context and Test Purpose**

The purpose of testing for BRAF pathogenic variants in individuals with unresectable or metastatic melanoma is to inform a decision whether to treat with BRAF or MEK tyrosine kinase inhibitors or with other standard treatments for metastatic melanoma. At the time of the early trials of targeted therapy for metastatic melanoma, cytotoxic chemotherapy (e.g., dacarbazine, temozolomide) was widely used to treat metastatic melanoma and was therefore considered a comparator, although it was never demonstrated to improve survival. Chemotherapy is now generally used only in second- or third-line settings or not at all. The current standard treatment for patients with metastatic melanoma includes immunotherapy,
which is effective in patients with and without BRAF V600 variants. Patients whose tumors contain a BRAF V600 pathogenic variant may receive a BRAF inhibitor and/or a MEK inhibitor instead of or following immunotherapy. There are no randomized controlled trials (RCTs) directly comparing BRAF and MEK inhibitors with immunotherapy, and no prospective data on optimal sequencing of BRAF and MEK inhibitors and immunotherapy for patients with a BRAF V600 pathogenic variant.

The question addressed in this evidence review is: Does testing for BRAF V600 pathogenic variants to select treatment improve the net health outcome in individuals with unresectable or metastatic melanoma?

The following PICOTS were used to select literature to inform this review.

**Patients**
The relevant population of interest is patients with stage IIIIC or stage IV unresectable or metastatic melanoma.

**Interventions**
The cobas 4800 BRAF V600 test and THxID BRAF kit are companion diagnostics approved by the U.S. Food and Drug Administration (FDA) for selecting patients for treatment with FDA-approved BRAF or MEK inhibitors.

**Comparators**
The comparator of interest is the standard treatment for metastatic melanoma without genetic testing for BRAF variants.

**Outcomes**
The primary outcomes of interest are overall survival (OS) and progression-free survival (PFS). False-positive BRAF test results could lead to inappropriate treatment with BRAF and/or MEK inhibitors, which have not been shown to be effective in patients without BRAF V600 pathogenic variants, and also could lead to delay in treatment with immunotherapy.

**Timing**
Due to the poor prognosis of metastatic melanoma, demonstration of improvement in survival outcomes at 6 months and 1 year are important.

**Setting**
Patients suspected of having melanoma should be urgently referred for management by specialists. A multidisciplinary group of specialists involved in caring for patients with metastatic melanoma includes dermatologists, oncologists, and plastic surgeons.

**Technically Reliable**
Assessment of technical reliability focuses on specific tests and operators and requires review of unpublished and often proprietary information. Review of specific tests, operators, and unpublished data are outside the scope of this evidence review, and alternative sources exist. This evidence review focuses on the clinical validity and clinical utility.

**Clinically Valid and Clinical Usefulness**
A test must detect the presence or absence of a condition, the risk of developing a condition in the future, or treatment response (beneficial or adverse). A test is clinically useful if the use of the results informs management decisions that improve the net health outcome of care. The net health outcome can be improved if patients receive correct therapy, or more effective therapy, or avoid unnecessary therapy, or avoid unnecessary testing.
Vemurafenib

The primary evidence of clinical validity and utility for the cobas 4800 BRAF V600 Mutation Test is provided by the phase 3 clinical trial of vemurafenib that enrolled patients testing positive for a V600 variant.

The BRIM-3 trial as reported by Chapman et al (2011) is summarized in Table 2. A total of 675 patients were randomized to vemurafenib (960 mg twice daily orally) or to dacarbazine (1000 mg/m² body surface area by intravenous infusion every 3 weeks) to determine whether vemurafenib would prolong the rate of OS or PFS compared with dacarbazine.37 All enrolled patients had unresectable, previously untreated stage IIIIC or IV melanoma with no active central nervous system metastases. Melanoma specimens from all patients tested positive for the BRAF V600E variant on the cobas 4800 BRAF V600 Mutation Test. Included were 19 patients with BRAF V600K variants and 1 with a BRAF V600D variant.

Tumor assessments, including computed tomography, were performed at baseline, at weeks 6 and 12, and every 9 weeks after that. Tumor responses were determined by investigators using Response Evaluation Criteria in Solid Tumors (RECIST), version 1.1. Primary end points were the rate of OS and PFS. An interim analysis was planned at 98 deaths and a final analysis at 196 deaths; the published report is the interim analysis. The data and safety monitoring board determined that both coprimary end points had met prespecified stopping criteria and recommended that patients in the dacarbazine group be allowed to crossover to receive vemurafenib. At the time the trial was halted, 118 patients had died; median survival had not been reached. Results for OS strongly favored vemurafenib, with a hazard ratio (HR) of 0.37 (95% confidence interval [CI], 0.26 to 0.55). Adverse events in the vemurafenib group included grade 2 or 3 photosensitivity skin reactions in 12% of patients and cutaneous squamous cell carcinoma in 18%. The results of this trial comprised the efficacy and safety data supporting vemurafenib submission to FDA and established safety and effectiveness of the cobas 4800 BRAF V600 Mutation Test, resulting in coapproval of both the drug and companion test.

Final OS results from BRIM-3 were reported by Chapman et al (2017).38 Eighty-four (25%) of the 338 dacarbazine patients crossed over to vemurafenib and overall 173 (51%) of the 338 patients in the dacarbazine group and 175 of the 337 patients (52%) in the vemurafenib group received subsequent anticancer therapies, most commonly ipilimumab. Median OS without censoring at crossover was 13.6 months (95% CI, 12.0 to 15.4) in vemurafenib vs 10.3 months (95% CI, 9.1 to 12.8 months) in dacarbazine (HR=0.81; 95% CI, 0.68 to 0.96; \( p=0.01 \)).

c Either intravenous dacarbazine 1000 mg/m² or intravenous paclitaxel 175 mg/m² every 3 weeks at investigator discretion.
d Compared encorafenib plus binimetinib with vemurafenib.

**Dabrafenib**

One phase 3, open-label RCT of dabrafenib for advanced (stage IV or unresectable stage III) melanoma has been published; the results of this trial are summarized in Table 2. The main objective of this RCT was to compare the efficacy of dabrafenib with standard dacarbazine treatment in patients who had BRAF V600E-variant metastatic melanoma. Two hundred fifty patients were randomized 3:1 to oral dabrafenib 150 mg twice daily or to intravenous dacarbazine 1000 mg/m² every 3 weeks. The primary outcome was PFS, and secondary outcomes were OS, objective response rate, and adverse events.

Median PFS for the dabrafenib and dacarbazine groups was 5.1 months and 2.7 months (p<0.001), respectively. OS did not differ significantly between groups: 11% of patients in the dabrafenib group died compared with 14% in the dacarbazine group (HR=0.61; 95% CI, 0.25 to 1.48). However, 28 (44%) patients in the dacarbazine arm crossed over at disease progression to receive dabrafenib. The objective response rate, defined as complete plus partial responses, was higher in the dabrafenib group (50% 95% CI, 42.4% to 57.1%) than in the dacarbazine group (6% 95% CI, 1.8% to 15.5%). Treatment-related adverse events of grade 2 or higher occurred in 53% of patients who received dabrafenib and in 44% of patients who received dacarbazine. Grade 3 and 4 adverse events were uncommon in both groups. The most common serious adverse events were cutaneous squamous cell carcinoma (7% vs none in controls); serious noninfectious, febrile drug reactions (3% grade 3 pyrexia vs none in controls); and severe...
hyperglycemia (>250-500 mg/dL) requiring medical management in nondiabetic patients or change in management of diabetic patients (6% vs none in controls).

**Trametinib**

The clinical efficacy and safety of trametinib were assessed in the phase 3, open-label METRIC trial. Patients with stage IV or unresectable stage IIIC cutaneous melanoma were randomized 2:1 to trametinib 2 mg orally once daily (n=214) or to chemotherapy (n=108), either dacarbazine 1000 mg/m² intravenously every 3 weeks or paclitaxel 175 mg/m² intravenously every 3 weeks at investigator discretion. Most patients (67%) were previously untreated. The primary efficacy end point was PFS; secondary end points included OS, overall response rate, and safety. Tumor assessments were performed at baseline and weeks 6, 12, 21, and 30 and then every 12 weeks.

Median PFS was 4.8 months (95% CI, 4.3 to 4.9 months) in the trametinib arm and 1.5 months (95% CI, 1.4 to 2.7 months) in the chemotherapy arm (p<0.001) (see Table 2). Although median OS had not been reached at the time of the report publication, 6-month survival was statistically longer in the trametinib group than in the chemotherapy group (p=0.01); 51 (47%) of 108 patients in the chemotherapy group had crossed over at disease progression to receive trametinib. Decreased ejection fraction or ventricular dysfunction was observed in 14 (7%) patients in the trametinib group; 2 patients had grade 3 cardiac events that led to permanent drug discontinuation. Twelve percent of the trametinib group and 3% of the chemotherapy group had grade 3 hypertension. Nine percent of patients in the trametinib group experienced ocular events (mostly grade 1 or 2), most commonly blurred vision (4%). The most common adverse events in the trametinib group were rash, diarrhea, peripheral edema, and fatigue; rash was grade 3 or 4 in 16 (8%) patients. Cutaneous squamous cell carcinoma was not observed during treatment.

**Combination BRAF Plus MEK Inhibitors**

**Dabrafenib and Trametinib**

The efficacy of combination dabrafenib plus trametinib treatment has been established with two phase 3 clinical trials. This combination agent was evaluated in the phase 3 open-label trial by Long et al (2014, 2015). In this trial, 4234 patients with unresectable stage IIIC or stage IV melanoma with a BRAF V600E or V600K variant were randomized to dabrafenib plus trametinib or dabrafenib plus placebo. The primary end point was PFS, as reported in a first publication, followed by a second publication in which longer term OS was reported.

Median PFS was 11.0 months in the dabrafenib plus trametinib group and 8.8 months in the dabrafenib-only group. The overall response rate was 67% in the dabrafenib plus trametinib group and 51% in the dabrafenib-only group. An interim OS analysis showed a statistically significant difference using standard statistical criteria, but the difference did not cross the prespecified stopping boundary. The rate of cutaneous squamous cell carcinoma was lower in the dabrafenib plus trametinib group (2% vs 9%), whereas pyrexia occurred in more patients (51% vs 28%). In the longer term study assessing OS, median survival was 25.1 months in the dabrafenib plus trametinib group and 18.7 months in the dabrafenib-only group.

Another phase 3 RCT, by Roberts et al (2015), compared dabrafenib plus trametinib with vemurafenib. A total of 704 patients with metastatic melanoma with BRAF V600E or V600K variants were randomized equally. The trial was terminated at a preplanned interim OS analysis. The OS rate at 12 months was 72% for dabrafenib plus trametinib and 65% for vemurafenib (p=0.005) (see Table 2). Median PFS was 11.4 months for dabrafenib plus trametinib and 7.3 months for vemurafenib (p<0.001). The objective response rate was 64% for dabrafenib plus trametinib and 51% for vemurafenib (p<0.001). Rates of severe adverse events were similar in both groups. Cutaneous squamous cell carcinoma and keratoacanthoma occurred in 1% of dabrafenib plus trametinib subjects and 18% of vemurafenib subjects.
Vemurafenib Plus Cobimetinib
A multicenter, randomized, double-blinded, placebo-controlled phase 3 trial evaluated vemurafenib plus cobimetinib in 495 patients with previously untreated, BRAF V600 variant-positive, unresectable or metastatic melanoma. All patients received vemurafenib 960 mg orally twice daily on days 1 to 28 and were randomized 1:1 to also receive cobimetinib 60 mg once daily on days 1 to 21 or to placebo. The primary outcome was PFS. Analyses were done on the intention-to-treat population. Median follow-up was 14 months (see Table 2). PFS was significantly increased with vemurafenib plus cobimetinib compared with vemurafenib plus placebo (median PFS, 12.3 months vs 7.2 months; HR=0.58; 95% CI, 0.46 to 0.72; p<0.001). Median OS was 22 months for vemurafenib plus cobimetinib and 17 months for vemurafenib plus placebo (HR=0.70; 95% CI, 0.55 to 0.90; p=0.005). Serious adverse events were reported in 92 (37%) patients in the vemurafenib plus cobimetinib group and 69 (28%) patients in the vemurafenib plus placebo group. The most common serious adverse events in the vemurafenib plus cobimetinib group were pyrexia and dehydration. The most common grade 3 or 4 adverse events occurring in the vemurafenib plus cobimetinib group were γ-glutamyl transferase increase, blood creatine phosphokinase increase, and alanine transaminase.

Encorafenib Plus Binimetinib
Dummer et al (2018) reported on results of a phase 3 COLUMBUS RCT comparing encorafenib, a BRAF inhibitor, alone or in combination with the MEK inhibitor binimetinib, with vemurafenib in patients who had advanced BRAF V600–variant unresectable or metastatic melanoma. The COLUMBUS trial was conducted in 162 hospitals in 28 countries between 2013 and 2015; patients were randomized (1:1:1) to oral encorafenib 450 mg once daily plus oral binimetinib 45 mg twice daily (n=192), oral encorafenib 300 mg once daily (n=194), or oral vemurafenib 960 mg twice daily (n=191). The primary outcome was PFS for encorafenib plus binimetinib vs vemurafenib. Analyses were done on the intention-to-treat population. Median follow-up was 17 months. PFS was significantly increased with encorafenib plus binimetinib compared with vemurafenib (median PFS=14.9 months vs 7.3 months in the vemurafenib group; HR=0.54; 95% CI, 0.41 to 0.71; p<0.001; see Table 2). OS was not reported. The most common grade 3 or 4 adverse events were increased γ-glutamyltransferase (9%), increased creatine phosphokinase (7%), and hypertension (6%) in the encorafenib plus binimetinib group; palmoplantar erythrodysesthesia syndrome (14%), myalgia (10%), and arthralgia (9%) in the encorafenib group; and arthralgia (6%) in the vemurafenib group.

BRAF Plus MEK Inhibitors vs Immunotherapy
For patients who are BRAF V600 variant–positive unresectable or metastatic melanoma, guidelines have suggested that both immunotherapy and BRAF plus MEK inhibitors are appropriate first-line therapies. We found no RCTs directly comparing BRAF and MEK inhibitors with immunotherapy. Network meta-analyses providing indirect comparisons are discussed below.

Amdahl et al (2016) reported on a network meta-analysis of RCTs comparing dabrafenib plus trametinib in previously untreated patients with other first-line treatments approved by Health Canada as of February 2015 (dabrafenib, vemurafenib, trametinib, ipilimumab, dacarbazine) for submission to Canadian reimbursement authorities. Seven studies (total N=2834 patients) were included. Bayesian network meta-analyses were performed to estimate HRs for PFS and OS. The combination of dabrafenib plus trametinib was associated with prolonged PFS and OS compared with all other first-line therapies analyzed. For PFS, the HRs (95% credible interval) favoring dabrafenib plus trametinib were: 0.23 (0.18 to 0.29) vs dacarbazine; 0.32 (0.24 to 0.42) vs ipilimumab plus dacarbazine; 0.52 (0.32 to 0.83) vs trametinib; 0.57 (0.48 to 0.69) vs vemurafenib; and 0.59 (0.50 to 0.71) vs dabrafenib. For OS, the HRs (95% credible interval) were: 0.41 (0.29 to 0.56) vs dacarbazine; 0.52 (0.38 to 0.71) vs ipilimumab plus dacarbazine; 0.68 (0.47 to 0.95) vs trametinib; 0.69 (0.57 to 0.84) vs vemurafenib; and 0.72 (0.60 to 0.85) vs dabrafenib. Nivolumab, pembrolizumab, and cobimetinib were not approved in Canada when the analysis was conducted.
Devji et al (2017) performed a network meta-analyses comparing first-line treatments and including RCTs of treatment-naive patients in which at least 1 intervention was a BRAF and a MEK inhibitor or an immune checkpoint inhibitor.48 Fifteen RCTs (total N=6662 patients) were included. Treatments were combined into drug classes: targeted therapy (BRAF and/or MEK inhibitor), immunotherapy (cytotoxic T-lymphocyte-associated antigen 4 [CTLA-4], programmed cell death protein 1 [PD-1], and/or granulocyte macrophage colony-stimulating factor), chemotherapy, and combinations of these treatments. Bayesian network meta-analyses were performed to calculate HRs for OS and PFS and odds ratios for objective response rates. The risk of bias for the included studies was low. BRAF plus MEK inhibition and PD-1 were both individually associated with improved OS compared with all other treatments except CTLA-4/granulocyte macrophage colony-stimulating factor; there was no significant difference in OS between BRAF plus MEK inhibition and PD-1 (HR=1.02; 95% credible interval, 0.72 to 1.45). The network meta-analysis showed a significant advantage of BRAF plus MEK inhibition compared with all other treatment strategies for PFS and objective response rate. Chemotherapy and PD-1 had the lowest risk of serious adverse events.

Pasquali et al (2017) also compared immune checkpoint inhibitors with BRAF targeted therapies in a network meta-analysis that included 12 RCTs (total N=6207 patients) reporting on anti-PD-1 antibodies, anti-CTLA-4 antibodies, BRAF inhibitors, and MEK inhibitors.49 BRAF plus MEK inhibition was associated with longer PFS compared with BRAF inhibition alone and immunotherapy (BRAF plus MEK vs anti-CTLA-4, HR=0.22; 95% CI, 0.12 to 0.41; BRAF vs MEK vs anti-PD-1 antibodies, HR=0.38; 95% CI, 0.20 to 0.72; BRAF plus MEK vs BRAF alone, HR=0.56; 95% CI, 0.44 to 0.70). Anti-PD-1 monoclonal antibodies were estimated to be the least toxic while the combination of anti-CTLA-4 and anti-PD-1 monoclonal antibodies was associated with the highest toxicity level.

Section Summary: Clinical Validity and Clinical Usefulness
RCTs of BRAF and MEK inhibitor therapy in patients selected by BRAF V600 variant testing have shown improvements in OS and PFS. Single-agent BRAF inhibitor treatment with vemurafenib and dabrafenib compared with chemotherapy has shown superior outcomes for response and PFS. Combination BRAF and MEK inhibitor treatment with vemurafenib plus cobimetinib or dabrafenib plus trametinib have shown superior OS compared with vemurafenib alone or dabrafenib alone. There are no RCTs directly comparing BRAF and MEK inhibitor therapy with immunotherapy as a first-line treatment for patients with BRAF pathogenic variants. Network meta-analyses including indirect comparisons have suggested that BRAF and MEK combination therapy might prolong PFS but with higher toxicity compared with immunotherapy.

Resected Stage III Melanoma
As was stated, clinical validity and clinical utility are evaluated together when treatments are developed for a specific biologic target that characterizes only some patients with a particular disease, and a test is codeveloped to identify diseased patients with that target. Therefore, phase 3 RCTs of targeted treatments are reviewed in this section in which either (1) testing for the BRAF variant was required for enrollment into the trial or (2) RCTs in which both patients with and without BRAF variants were enrolled and treatment effects stratified by variant status are reported.

Clinical Context and Test Purpose
The purpose of testing for BRAF pathogenic variants in individuals with resected stage III melanoma is to inform a decision whether to use adjuvant treatment with BRAF and/or MEK tyrosine kinase inhibitors after surgical resection. Observation, as well as treatment with nivolumab or ipilimumab, are also options for resected stage III melanoma. There are no RCTs directly comparing BRAF and MEK inhibitors with immunotherapy.

The question addressed in this evidence review is: Does testing for BRAF V600 pathogenic variants to select treatment improve the net health outcome in individuals with resected stage III melanoma?
The following PICOTS were used to select literature to inform this review.

**Patients**
The relevant population of interest is patients with stage III resected melanoma.

**Interventions**
The cobas 4800 BRAF V600 test and THxID BRAF kit are FDA-approved companion diagnostics for selecting patients for treatment with FDA-approved BRAF or MEK inhibitors.

**Comparators**
The comparator of interest is the standard treatment for resected stage III melanoma without genetic testing for BRAF variants, which includes observation, checkpoint inhibitor immunotherapy, or high-dose interferon alfa.

**Outcomes**
The primary outcome of interest is recurrence. False-positive BRAF test results could lead to inappropriate treatment with BRAF and/or MEK inhibitors, which have not been shown to be effective in patients without BRAF V600 pathogenic variants, and also could lead to delay in treatment with immunotherapy.

**Timing**
The time point of interest for outcomes is at least 3 years.

**Setting**
Patients with resected stage III melanoma would receive care from dermatologists and oncologists.

**Technically Reliable**
Assessment of technical reliability focuses on specific tests and operators and requires review of unpublished and often proprietary information. Review of specific tests, operators, and unpublished data are outside the scope of this evidence review, and alternative sources exist. This evidence review focuses on the clinical validity and clinical utility.

**Clinically Valid and Clinical Usefulness**
A test must detect the presence or absence of a condition, the risk of developing a condition in the future, or treatment response (beneficial or adverse). A test is clinically useful if the use of the results informs management decisions that improve the net health outcome of care. The net health outcome can be improved if patients receive correct therapy, or more effective therapy, or avoid unnecessary therapy, or avoid unnecessary testing.

Two RCTs of BRAF and/or MEK inhibitors in patients with resected stage III BRAF-variant melanoma, have been reported. Trial design characteristics are reported in Table 3; results are reported in Table 4. An appraisal of study relevance as well as design and conduct gaps are reported in Tables 5 and 6.

Long et al (2017) reported on results of COMBI-AD, a phase 3 RCT comparing adjuvant combination therapy using dabrafenib plus trametinib with placebo in 870 patients who had stage III melanoma with BRAF V600E or V600K variants. In 2013 and 2014 when patients were being enrolled in COMBI-AD, observation was the standard of care after resection of stage III melanoma in most countries. With a median follow-up of 2.8 years, the 3-year rate of relapse-free survival was 58% in the combination group and 39% in the placebo group (HR=0.47; 95% CI, 0.39 to 0.58; p<0.001). OS rates at 3 years were 86% and 77%, respectively (HR=0.57; 95% CI, 0.42 to 0.79; p<0.001).

Maio et al (2018) reported on results of BRIM8, a phase 3 RCT comparing adjuvant vemurafenib monotherapy with placebo in 498 patients who had stage IIC, IIIA, IIIB, or IIIC BRAF V600
variant-positive melanoma. Patients with stage IIC, IIIA, or IIIB disease were enrolled in cohort 1 (n=314), and patients with stage IIIC disease were enrolled in cohort 2 (n=184). As stated previously, during enrollment, observation was standard care for stage III melanoma. A hierarchical testing strategy was prespecified for the primary outcome (disease-free survival) based on the assumption that observing a biologic effect in higher risk disease (i.e., cohort 2) would suggest a treatment effect across the continuum of melanoma given the effect is already established in metastatic melanoma. In the hierarchical strategy, only a p value of 0.05 or less in cohort 2 would allow for results in cohort 1 to be considered significant. The median trial follow-up was 34 months (interquartile range, 26-42 months) in cohort 2 and 31 months (interquartile range, 26-41 months) in cohort 1. In cohort 2, median disease-free survival was 23 months (95% CI, 19 to 27 months) in the vemurafenib group and 15 months (95% CI, 11 to 36 months) in the placebo group (HR=0.80; 95% CI, 0.54 to 1.18; p=0.26). In cohort 1, median disease-free survival was not reached (95% CI, not estimable) in the vemurafenib group and 37 months (95% CI, 21 to not estimable) in the placebo group (HR=0.54; 95% CI, 0.37 to 0.78); however, this result cannot be considered statistically significant because of the prespecified hierarchical testing strategy.

Section Summary: Clinical Valid and Clinical Usefulness

RCTs of BRAF and MEK inhibitor therapy in stage III melanoma patients selected by BRAF V600 variant testing have shown reductions in recurrence risk. One well-conducted RCT of combination BRAF and MEK inhibitor treatment with dabrafenib plus trametinib has shown superior for recurrence risk and OS in BRAF variant–positive, stage III patients compared with placebo. Single-agent BRAF inhibitor treatment using vemurafenib compared with placebo showed numeric benefit for disease-free survival in patients with stage IIC, IIIA, or IIIB BRAF V600 variant–positive melanoma but this result must be considered exploratory given the lack of statistically significant benefit in stage IIIC disease and the hierarchical statistical testing strategy. There are no RCTs directly comparing BRAF and MEK inhibitor therapy with immunotherapy as an adjuvant treatment for stage III patients with BRAF pathogenic variants.

Glioma

When treatment is developed for a specific biologic target that characterizes only some patients with a particular disease, and a test is codeveloped to identify diseased patients with that target, clinical validity and clinical utility cannot be evaluated separately. Rather, clinical studies of treatment benefit, which use the test to select patients, provide evidence of both clinical validity and clinical utility. We reviewed the phase 3 clinical trials of treatments in which testing for the BRAF variant was required for selection into the trial. In the absence of clinical trials in which both patients with and without BRAF variants are entered into RCTs of novel therapies, we cannot be certain that the test has clinical utility because it is unknown whether the treatment would be effective in patients without BRAF variant. However, patients without BRAF variants have not been enrolled in clinical trials of BRAF inhibitors.

Clinical Context and Test Purpose

The purpose of testing for BRAF pathogenic variants in individuals with glioma is to inform a decision whether to treat with BRAF or MEK inhibitors or with other standard treatments for glioma. Standard treatment for patients with glioma includes surgical resection followed by radiotherapy and/or chemotherapy with temozolomide.

The question addressed in this evidence review is: Does testing for BRAF pathogenic variants to select treatment improve the net health outcome in individuals with glioma?

The following PICOTS were used to select literature to inform this review.

Patients
The relevant population of interest is patients with glioma, particularly patients for whom adjuvant therapy following resection is indicated or for whom resection is not possible.

Interventions
The intervention of is genetic testing for BRAF V600 pathogenic variants to select treatments.

Comparators
The comparator of interest is the standard treatment for glioma without genetic testing for BRAF variants.
2.04.77 BRAF Gene Variant Testing to Select Melanoma or Glioma Patients for Targeted Therapy

Page 16 of 25

Outcomes
The primary outcomes of interest are OS and PFS. False-positive BRAF test results could lead to inappropriate treatment with BRAF and/or MEK inhibitors, may not be effective in patients without BRAF V600 pathogenic variants, and could also lead to delay in treatment with chemotherapy.

Timing
For low-grade glioma, the time point of interest for survival outcomes is at least 5 years. Due to the poor prognosis of high-grade glioma, demonstration of improvement in survival outcomes at 1 year is important.

Setting
Patients diagnosed with gliomas should be referred for treatment by specialists experienced in the management of glioma. This will likely consist of a multidisciplinary group of physicians including neurologists, neurosurgeons, oncologists, and radiation oncologists.

Technically Reliable
Assessment of technical reliability focuses on specific tests and operators and requires review of unpublished and often proprietary information. Review of specific tests, operators, and unpublished data are outside the scope of this evidence review, and alternative sources exist. This evidence review focuses on the clinical validity and clinical utility.

Clinical Validity and Clinical Usefulness
A test must detect the presence or absence of a condition, the risk of developing a condition in the future, or treatment response (beneficial or adverse). A test is clinically useful if the use of the results informs management decisions that improve the net health outcome of care. The net health outcome can be improved if patients receive correct therapy, or more effective therapy, or avoid unnecessary therapy, or avoid unnecessary testing.

Sorafenib
Sorafenib is a multikinase inhibitor with potent in vitro activity against both BRAF wild-type and V600E variants as well as vascular endothelial growth factor receptors, platelet-derived growth factor receptors, and c-KIT. Several phase 2, single-arm prospective studies have investigated the use of sorafenib in newly diagnosed and recurrent, adult and pediatric, low- and high-grade gliomas in various combinations with other treatments. Results have not shown sorafenib to be effective. Most studies did not report BRAF V600 variant status. Table 7 describes select prospective studies of sorafenib in glioma.

a Study terminated early.

Vemurafenib, Dabrafenib, and Trametinib
Several case reports and small case series have suggested clinical benefit with vemurafenib, dabrafenib, and trametinib in patients with glioma and BRAF V600 pathogenic variants. Ongoing early-phase studies evaluating BRAF and MEK inhibitors are listed in Table 8.

Hyman et al (2015) published results of a multicenter phase 2 “basket” study of vemurafenib in BRAF V600 variant-positive nonmelanoma cancers.60 A total of 122 patients with BRAF V600 pathogenic variants were enrolled, including 8 patients with gliomas. The response was assessed by site investigators using RECIST criteria. Of the 8 glioma patients, 2 died before the 1-month evaluation; 4 had stable disease at 12, 6, 4, and 3 months and 2 had progressive disease at 2 and 7 months, all respectively.

Section Summary: Clinical Validity and Clinically Useful
Studies of sorafenib in patients with newly diagnosed and recurrent gliomas combined with various other treatments have not shown benefit, although most did not report BRAF V600 status. Evaluation of the BRAF and MEK inhibitors vemurafenib, dabrafenib, and trametinib in patients with gliomas has been limited to 1 phase 2 “basket” study (including 8 patients with glioma), case reports, and small case series. Several early-phase studies are ongoing. Phase 3 clinical trials of targeted treatments are needed in which either (1) testing for the BRAF variant was required for selection into the trial or (2) patients with and without a BRAF variant are included, and testing for treatment interactions by variant status are prespecified.

Summary of Evidence
For individuals who have unresectable or metastatic melanoma who receive BRAF gene variant testing to select treatment with BRAF or MEK inhibitor combination therapy, the evidence includes randomized trials. Relevant outcomes are overall survival, disease-specific survival, and test accuracy. Randomized phase 3 trials of BRAF inhibitor therapy in patients selected on the basis of BRAF variant testing have shown improvements in overall survival and progression-free survival. Single-agent BRAF inhibitor treatment compared with nontargeted treatments have shown superior outcomes for most end points. Combination BRAF and MEK inhibitor treatment with vemurafenib plus cobimetinib or dabrafenib plus trametinib have shown superior overall survival compared with vemurafenib or dabrafenib alone. Data showing treatment effects in
patients without BRAF variants do not exist; therefore, BRAF variant testing is required to identify patients to whom these trial results apply. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have resected stage III melanoma who receive BRAF gene variant testing to select treatment with BRAF or MEK inhibitors, the evidence includes randomized trials. Relevant outcomes are overall survival, disease-specific survival, and test accuracy. One randomized phase 3 trial of BRAF and MEK combination therapy with dabrafenib plus trametinib in patients selected by BRAF variant testing has shown improvements in recurrence-free survival and overall survival compared with placebo. One randomized phase 3 trial of vemurafenib monotherapy did not find statistically significant differences in disease-free survival in patients with stage IIIC disease. In patients with stage IIC, IIIA, or IIIB disease, median disease-free survival was prolonged with vemurafenib, but this result was considered exploratory. Data showing treatment effects in patients without BRAF variants do not exist; therefore, BRAF variant testing is required to identify patients to whom these trial results apply. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have glioma who receive BRAF gene variant testing to select treatment with BRAF or MEK inhibitors, the evidence includes small, prospective, uncontrolled studies and case reports. Relevant outcomes are overall survival, disease-specific survival, and test accuracy. Studies assessing the use of sorafenib in patients with newly diagnosed and recurrent gliomas combined with various other treatments have not shown benefit, although most did not report BRAF V600 variant status. Evaluation of the BRAF and MEK inhibitors vemurafenib, dabrafenib, and trametinib in patients with gliomas has been limited to a phase 2 “basket” study, including 8 patients with glioma, as well as case reports and small case series. Early reports have suggested clinical benefit, but confirmatory randomized controlled trials are lacking. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Supplemental Information**

**Practice Guidelines and Position Statements**

National Comprehensive Cancer Network Guidelines for melanoma (v.2.2018) recommends BRAF variant status should be tested “using an FDA-approved [Food and Drug Administration] test or by a facility approved by CLIA [Clinical Laboratory Improvement Amendments] facility.” Combination dabrafenib plus trametinib and combination vemurafenib plus cobimetinib therapies have a category 1 recommendation as a preferred regimen for advanced or metastatic melanoma. Vemurafenib and dabrafenib also have category 1 recommendations for advanced or metastatic melanoma. The National Comprehensive Cancer Network also recommends dabrafenib plus trametinib combination therapy as an option for patients with stage III melanoma who have a BRAF V600E-activating variant and sentinel lymph node metastasis greater than 1 mm (category 1).

Network guidelines for central nervous system cancers (v.1.2018) indicate the following on the use of BRAF molecular markers to guide treatment decisions for primary brain cancers: “BRAF V600E tumors may respond to BRAF inhibitors such as vemurafenib, but comprehensive clinical trials are still ongoing.”

**U.S. Preventive Services Task Force Recommendations**

Not applicable.

**Medicare National Coverage**

There is no national coverage determination. In the absence of a national coverage determination, coverage decisions are left to the discretion of local Medicare carriers.

**Ongoing and Unpublished Clinical Trials**

Some currently unpublished trials that might influence this review are listed in Table 8.

BRAF Gene Variant Testing to Select Melanoma or Glioma Patients for Targeted Therapy

**Documentation for Clinical Review**

**Please provide the following documentation (if/when requested):**

- History and physical and/or consultation notes including:
  - Differential diagnosis, prognosis, and cancer staging
  - Specific FDA-approved test requested (e.g., cobas 4800 BRAF V600 Mutation Test)
  - Clinical justification/reason for testing
  - Treatment plan
- Laboratory and pathology reports (including cancer staging and FDA-approved BRAF V600 mutation test results)

**Post Service**

- Results/reports of tests performed

**Coding**

This Policy relates only to the services or supplies described herein. Benefits may vary according to product design; therefore, contract language should be reviewed before applying the terms of the Policy. Inclusion or exclusion of codes does not constitute or imply member coverage or provider reimbursement.

**MN/IE**

The following services may be considered medically necessary in certain instances and investigational in others. Services may be considered medically necessary when policy criteria are met. Services may be considered investigational when the policy criteria are not met or when the code describes application of a product in the position statement that is investigational.

Definitions of Decision Determinations

**Medically Necessary:** A treatment, procedure, or drug is medically necessary only when it has been established as safe and effective for the particular symptoms or diagnosis, is not investigational or experimental, is not being provided primarily for the convenience of the patient or the provider, and is provided at the most appropriate level to treat the condition.

**Investigational/Experimental:** A treatment, procedure, or drug is investigational when it has not been recognized as safe and effective for use in treating the particular condition in accordance with generally accepted professional medical standards. This includes services where approval by the federal or state governmental is required prior to use, but has not yet been granted.

**Split Evaluation:** Blue Shield of California/Blue Shield of California Life & Health Insurance Company (Blue Shield) policy review can result in a split evaluation, where a treatment, procedure, or drug will be considered to be investigational for certain indications or conditions, but will be deemed safe and effective for other indications or conditions, and therefore potentially medically necessary in those instances.

Prior Authorization Requirements (as applicable to your plan)

Within five days before the actual date of service, the provider must confirm with Blue Shield that the member's health plan coverage is still in effect. Blue Shield reserves the right to revoke an authorization prior to services being rendered based on cancellation of the member's eligibility. Final determination of benefits will be made after review of the claim for limitations or exclusions.

Questions regarding the applicability of this policy should be directed to the Prior Authorization Department. Please call (800) 541-6652 or visit the provider portal at www.blueshieldca.com/provider.

Disclaimer: This medical policy is a guide in evaluating the medical necessity of a particular service or treatment. Blue Shield of California may consider published peer-reviewed scientific literature, national
guidelines, and local standards of practice in developing its medical policy. Federal and state law, as well as contract language, including definitions and specific contract provisions/exclusions, take precedence over medical policy and must be considered first in determining covered services. Member contracts may differ in their benefits. Blue Shield reserves the right to review and update policies as appropriate.
